# ON THE APPLICATION OF CERTAIN INTEGRO-DIFFERENTIAL OPERATORS

In the present note we give formulations of a number of new results in the theory of Dirichlet series and in the theory of quasianalytic classes of functions. These results are obtained by introducing special integro-differential operators connected with the concept of fractional integration in the sense of Riemann–Liouville or H. Weyl.

1°. Let the function  $F(\sigma)$  be defined and continuous on the half-axis  $(\sigma_0, +\infty)$ . For any  $\alpha > 0$  define the operator

$$\frac{d_e^{-\alpha} F(\sigma)}{d_e \sigma^{-\alpha}} \equiv \frac{1}{\Gamma(\alpha)} \int_{\sigma}^{+\infty} (e^{-\sigma} - e^{-u})^{\alpha-1} e^{-u} F(u) du, \quad (1)$$

calling it the fractional integral of the function  $F(\sigma)$  of order  $\alpha$  with endpoint at  $+\infty$ . It is easy to see that

$$\lim_{\alpha \rightarrow +0} \frac{d_e^{-\alpha} F(\sigma)}{d_e \sigma^{-\alpha}} \equiv F(\sigma),$$

and therefore it is natural to regard the function  $F(\sigma)$  itself as the integral of order zero.

Let the sequence  $\{\mu_n\}$  ( $n \geq 0$ ) satisfy the condition

$$\mu_0 = 0; \quad 0 < \mu_{k+1} - \mu_k \leq 1 \quad (k \geq 0); \quad \lim_{k \rightarrow \infty} \mu_k = +\infty. \quad (2)$$

Denote  $\alpha_k = 1 - (\mu_k - \mu_{k-1})$  ( $k = 1, 2, \dots$ ), and introduce the operators

$$L^{(\mu_0)} F(\sigma) \equiv F(\sigma), \quad L^{(\mu_k)} F(\sigma) \equiv -\frac{d_e^{-\alpha_k}}{d_e \sigma^{-\alpha_k}} \left\{ e^{\sigma} \frac{d}{d\sigma} L^{(\mu_{k-1})} F(\sigma) \right\} \quad (k \geq 1), \quad (3)$$

assuming that all of them exist and are continuous on the half-axis  $(\sigma_0, +\infty)$ .

We shall agree to say that the function  $L^{(\mu_k)}F(\sigma)$  is continuous on  $(\sigma_0, +\infty]$  if: 1) it is continuous on the interval  $(\sigma_0, +\infty)$ ; 2) there exists a finite limit

$$L^{(\mu_k)}F(+\infty) = \lim_{\sigma \rightarrow +\infty} L^{(\mu_k)}F(\sigma).$$

We shall say that  $F(\sigma) \in \mathcal{L}(\mu_n; \sigma_0)$  if all the functions  $L^{(\mu_k)}F(\sigma)$  ( $k \geq 0$ ) exist and are continuous on  $(\sigma_0, +\infty]$ , while the functions

$$e^\sigma \frac{d}{d\sigma} L^{(\mu_k)}F(\sigma) \quad (k = 0, 1, 2, \dots)$$

are continuous and absolutely integrable on  $(\sigma_1, +\infty)$ , where  $\sigma_1 > \sigma_0$  is arbitrary.

**Theorem 1.** If  $F(\sigma) \in \mathcal{L}(\mu_n; \sigma_0)$ , then for any  $n \geq 0$  and  $\sigma \in (\sigma_0, +\infty]$  the formula holds

$$F(\sigma) = \sum_{k=0}^n \frac{L^{(\mu_k)}F(+\infty)}{\Gamma(1 + \mu_k)} e^{-\mu_k \sigma} + \frac{1}{\Gamma(\mu_{n+1})} \int_{\sigma}^{+\infty} (e^{-\sigma} - e^{-u})^{\mu_{n+1}-1} e^{-u} L^{(\mu_{n+1})}F(u) du. \quad (4)$$

This formula is, in a certain sense, an analogue of Taylor's formula and, as is not difficult to see, in the particular case when  $\mu_n = n$  ( $n = 0, 1, 2, \dots$ ), after the change of variable  $e^{-\sigma} = x$ , coincides with it.

From the class  $\mathcal{L}(\mu_n; \sigma_0)$  we single out the subclass  $\mathcal{L}^*(\mu_n; \sigma_0)$  of those functions  $F(\sigma)$  for which, as  $n \rightarrow \infty$ , the integral remainder term in formula (4) tends uniformly to zero in any interval  $[\sigma_1, +\infty] \subset (\sigma_0, +\infty)$ . Consequently, if  $F(\sigma) \in \mathcal{L}^*(\mu_n; \sigma_0)$ , then the expansion into a Dirichlet series is valid:

$$F(\sigma) = \sum_{k=0}^{\infty} \frac{L^{(\mu_k)}F(+\infty)}{\Gamma(1 + \mu_k)} e^{-\mu_k \sigma}, \quad (5)$$

uniformly convergent on any half-line  $[\sigma_1, +\infty] \subset (\sigma_0, +\infty)$ . It is clear, moreover, that if  $F(\sigma) \in \mathcal{L}^*(\mu_n; \sigma_0)$ , then it admits an analytic continuation to the whole half-plane  $\sigma = \operatorname{Re} s > \sigma_0$  ( $s = \sigma + it$ ), and the expansion (5) remains valid in the same half-plane.

The following criterion of necessary-and-sufficient type holds for the expansibility of functions in a Dirichlet series with respect to the given system  $\{e^{-\mu_k s}\}$ .

**Theorem 2.** Let the sequence  $\{\mu_n\}$  ( $n \geq 0$ ) satisfy condition (1).

a) If  $F(\sigma) \in \mathcal{L}(\mu_n; \sigma_0)$  and, in addition,

$$\sup_{(\sigma_0, +\infty]} |L^{(\mu_k)} F(\sigma)| \leq M e^{-\sigma_0 \mu_k} \Gamma(1 + \mu_k) \quad (k \geq 0),$$

then  $F(\sigma) \in \mathcal{L}^*(\mu_n; \sigma_0)$ , i.e. the expansion

$$F(\sigma) = \sum_{k=0}^{\infty} \frac{L^{(\mu_k)} F(+\infty)}{\Gamma(1 + \mu_k)} e^{-\mu_k \sigma}, \quad \sigma \in (\sigma_0, +\infty],$$

holds.

b) If, in addition to (1), the sequence  $\{\mu_n\}$  also satisfies the condition

$$\limsup_{k \rightarrow \infty} \frac{\log k}{\mu_k} < l < +\infty \quad (6)$$

and the expansion

$$F(\sigma) = \sum_{k=0}^{\infty} a_k e^{-\mu_k \sigma}, \quad \sigma \in (\sigma_0, +\infty],$$

holds, then for  $\sigma_1 = \sigma_0 + l$  one has  $F(\sigma) \in \mathcal{L}(\mu_n; \sigma_1)$ ; moreover,

$$\sup_{(\sigma_1, +\infty]} |L^{(\mu_k)} F(\sigma)| \leq A B^{\mu_k} \Gamma(1 + \mu_k) \quad (k \geq 0),$$

$$a_k = \frac{L^{(\mu_k)} F(+\infty)}{\Gamma(1 + \mu_k)} \quad (k \geq 0).$$

In the case when the condition  $0 < \mu_{k+1} - \mu_k \leq 1$  ( $k \geq 0$ ) is not fulfilled, the following result holds.

**Theorem 3.** Let the sequence  $\{\mu_n\}$  ( $n \geq 0$ ) satisfy the conditions

$$\mu_0 \geq 0; \quad 0 < \mu_{k+1} - \mu_k \quad (k \geq 0); \quad \lim_{k \rightarrow \infty} \mu_k = +\infty. \quad (7)$$

a) If  $F(\sigma)$  is defined on  $(\sigma_0, +\infty)$  and there exists an extension of  $\{\mu_n\}$  to a sequence  $\{\mu_n^*\}$  satisfying conditions (1), such that:

- 1)  $F(\sigma) \in \mathcal{L}(\mu_n^*; \sigma_0)$ ;
- 2)

$$\sup_{(\sigma_0, +\infty]} |L^{(\mu_k)} F(\sigma)| \leq M e^{-\sigma_0 \mu_k} \Gamma(1 + \mu_k) \quad (k \geq 0);$$

3)  $L^{(\mu_k^*)}F(+\infty) = 0$ , if  $\mu_k^* \notin \{\mu_n\}$ ,

then the expansion into a Dirichlet series is valid:

$$F(\sigma) = \sum_{k=0}^{\infty} \frac{L^{(\mu_k)}F(+\infty)}{\Gamma(1 + \mu_k)} e^{-\mu_k \sigma}, \quad \sigma \in (\sigma_0, +\infty].$$

In this case  $F(\sigma)$  can be analytically continued to the half-plane  $\sigma = \operatorname{Re} s > \sigma_0$  ( $s = \sigma + it$ ), and the expansion remains valid in the whole half-plane  $\sigma = \operatorname{Re} s > \sigma_0$ .

b) Let  $\{\mu_n\}$  ( $n \geq 0$ ) satisfy conditions (7) and (6), and suppose that there is an expansion

$$F(\sigma) = \sum_{k=0}^{\infty} a_k e^{-\mu_k \sigma}, \quad \sigma \in (\sigma_0, +\infty).$$

For any completion of  $\{\mu_n\}$  to a sequence  $\{\mu_n^*\}$  satisfying conditions (1) and

$$\limsup_{k \rightarrow +\infty} \frac{\log k}{\mu_k^*} < l^* < +\infty,$$

the following assertions hold for  $\sigma^* = \sigma_0 + l^*$ :

1)  $F(\sigma) \in \mathcal{L}(\mu_n^*; \sigma^*)$ ;

2)

$$\sup_{(\sigma^*, +\infty)} |L^{(\mu_k)}(F(\sigma))| \leq AB^{\mu_k} \Gamma(1 + \mu_k) \quad (k \geq 0);$$

3)

$$a_k = \frac{L^{(\mu_k)}F(+\infty)}{\Gamma(1 + \mu_k)} \quad (k \geq 0),$$

where  $L^{(\mu_k)}F(\sigma) = L^{(\mu_{n_k}^*)}F(\sigma)$ , if  $\mu_k = \mu_{n_k}^*$ .

2°. For a function  $f(x)$ , defined and continuous on the half-line  $[0, +\infty)$ , and for a given sequence  $\{\alpha_k\}$  ( $k \geq 0$ ), where  $0 \leq \alpha_k < 1$  ( $k \geq 0$ ), we introduce the operators

$$D^0 f(x) \equiv \frac{d^{-\alpha_0}}{dx^{-\alpha_0}} f(x); \quad D^{(k)} f(x) \equiv \frac{d^{-\alpha_k}}{dx^{-\alpha_k}} \frac{d}{dx} D^{(k-1)} f(x) \quad (k \geq 0),$$

where, for  $\alpha > 0$ ,

$$\frac{d^{-\alpha}}{dx^{-\alpha}} f(x) \equiv \frac{1}{\Gamma(\alpha)} \int_0^x (x-t)^{\alpha-1} f(t) dt$$

is the fractional integral of order  $\alpha$  of the function  $f(x)$  in the Riemann-Liouville sense.\*

We shall call the function  $D^{(k)}f(x)$  (if it exists) the  $k$ -th generalized derivative of  $f(x)$  with respect to the given sequence  $\{\alpha_k\}$ . We shall say that  $f(x) \in C\{\alpha_k\}$  if the functions  $D^{(k)}f(x)$  ( $k \geq 0$ ) are continuous on the half-line  $[0, +\infty)$ , and the functions

$$\frac{d}{dx} D^{(k)}f(x) \quad (k \geq 0)$$

are continuous on  $(0, +\infty)$  and absolutely integrable on every interval  $[0, \delta]$  ( $\delta \geq 0$ ).

Let  $\{m_n\}$  ( $n \geq 0$ ) be some sequence of positive numbers. We assign to the class  $C_{m_n}\{\alpha_k\}$  all those functions  $f(x)$  from the class  $C\{\alpha_k\}$  for which:

a)

$$|D^{(k)}f(x)| \leq AB \sum_1^{k(1-\alpha_i)} m_k e^{Cx} \quad (k \geq 0), \quad 0 \leq x < +\infty,$$

where  $A$ ,  $B$ , and  $C$  are constants depending on the given function  $f(x)$ ;

b)

$$e^{-Cx} \left| \frac{d}{dx} D^{(k)}f(x) \right| \in L_1(0, +\infty) \quad (k \geq 0).$$

We shall say that the set of functions  $C_{m_n}\{\alpha_k\}$  constitutes a quasi-analytic class in the generalized sense if, for any functions  $f_1(x)$  and  $f_2(x) \in C_{m_n}\{\alpha_k\}$ , the equalities  $D^{(k)}f_1(0) = D^{(k)}f_2(0)$  ( $k \geq 0$ ) imply the identity

$$f_1(x) \equiv f_2(x), \quad 0 \leq x < +\infty.$$

The following assertion holds—an analogue of the well-known Carleman-Ostrovsky theorem.

---

\* It is easy to see the connection between the operators  $L^{(\mu_k)}F(\sigma)$  and  $D^{(k)}f(x)$ , if one makes the change of variable  $x = e^{-\sigma}$ .

**Theorem 4.** For the quasianalyticity of the class  $C_{m_n}\{\alpha_k\}$  it is necessary and sufficient that

$$\int_1^{+\infty} \frac{\log T_\alpha(r)}{r^2} dr = +\infty,$$

where

$$T_\alpha(r) = \sup_{n \geq 1} \frac{r^{\sum_1^n (1-\alpha_k)}}{m_n}.$$

3°. Let  $f(x)$  be given on  $(-\infty, +\infty)$ .

The **Weyl integral of order**  $\alpha > 0$  of the function  $f(x)$  is the function

$$W^\alpha f(x) = \frac{1}{\Gamma(\alpha)} \int_{-\infty}^x (x-t)^{\alpha-1} f(t) dt.$$

It is natural to set  $W^0 f(x) \equiv f(x)$ .

For a given sequence  $\{\alpha_k\}$  ( $k \geq 0$ ;  $0 \leq \alpha_k < 1$ ) we introduce the operations

$$R^{(0)} f(x) \equiv W^{\alpha_0} f(x); \quad R^{(k)} f(x) \equiv W^{\alpha_k} \frac{d}{dx} R^{(k-1)} f(x) \quad (k \geq 1).$$

It is easy to see that if  $\alpha_k = 0$  ( $k \geq 0$ ), then  $R^{(k)} f(x) \equiv f^{(k)}(x)$ .

Let the function  $p(x)$  be defined and continuously differentiable on the half-axis  $[0, +\infty)$ , and let  $\lim_{t \rightarrow +\infty} p'(t) = +\infty$ , while the function  $q(x)$ , as in <sup>(1)</sup>, is conjugate to  $p(x)$  in the sense of Young. Let, further,  $\{m_n\}$  be some sequence of positive numbers.

We assign to the class  $C_{m_n}\{p(x); \alpha_k\}$  all functions satisfying the conditions:

- a) The functions  $R^{(k)} f(x)$  and  $\frac{d}{dx} R^{(k)} f(x)$  exist and are continuous on the whole axis  $(-\infty, +\infty)$ ;
- b)

$$|R^{(k)} f(x)| \leq m_k \omega_f(x) e^{-p_1(x)} \quad (k = 0, 1, 2, \dots), \quad -\infty < x < +\infty,$$

where  $\omega_f(x) \geq 0$  is summable on  $(-\infty, +\infty)$ , and  $p_1(x) \equiv p(|x|)$  for  $x \leq 0$ , while  $p_1(x) \geq C_0$  for  $x > 0$  ( $C_0$  is a real constant);

- c)

$$\left| (1+x^2) \frac{d}{dx} R^{(k)} f(x) \right| \leq C_k \quad (k = 0, 1, 2, \dots), \quad -\infty < x < +\infty,$$

where  $C_k > 0$  are some constants.

**Theorem 5.** The class  $C_{m_n} \{p(x); \alpha_k\}$  is empty, in other words, contains only the function  $f(x) \equiv 0$ ,  $-\infty < x < +\infty$ , if

$$\lim_{R \rightarrow +\infty} \inf \left\{ \frac{q(R)}{R} - \frac{2}{\pi} \int_1^R \frac{\log T_\alpha(r)}{r^2} dr \right\} = -\infty,$$

where

$$T_\alpha(r) = \sup_{n \geq 1} \frac{r^{\sum_1^n (1-\alpha_k)}}{m_n}.$$
