**ASYMPTOTICS OF SOLUTIONS OF CERTAIN BOUNDARY-VALUE PROBLEMS FOR QUASILINEAR EQUATIONS WITH A SMALL PARAMETER AT THE HIGHEST DERIVATIVE**

*(Presented by Academician I. G. Petrovskii, July 4, 1958)*

**1. Statement of the problem.** Consider the equation

$$\mu \frac{d^2 y}{dt^2} = -A(t, y) \frac{dy}{dt} + B(t, y), \quad (1)$$

where  $\mu \geq 0$  is a small parameter. A number of works are devoted to the study of the solution of equation (1) and of equations of a more general form under various boundary conditions (see, for example, <sup>(1)</sup>).

Let the boundary conditions be given as

$$\text{I. } y'(0) = 0, \quad y(1) = 0; \quad (2')$$

$$\text{II. } y(0) = 0, \quad y(1) = 0. \quad (2'')$$

We shall denote the corresponding solutions of equation (1) by  $y_{\text{I}}(t, \mu)$ ,  $y_{\text{II}}(t, \mu)$ .

Putting  $\mu = 0$  in (1), we obtain the degenerate equation

$$A(t, u) \frac{dy}{dt} = B(t, u), \quad (3)$$

whose solution we define by the condition

$$u(1) = 0. \quad (4)$$

In <sup>(1)</sup>, under certain restrictions on the right-hand side of (1) (see below), it is shown that

$$\lim_{\mu \rightarrow 0} y_{\text{I}}(t, \mu) = u(t), \quad 0 \leq t \leq 1; \quad (5')$$

$$\lim_{\mu \rightarrow 0} y_{\text{II}}(t, \mu) = u(t), \quad 0 < t \leq 1. \quad (5'')$$

Thus, for sufficiently small values of  $\mu$ ,  $u(t)$  can serve as an approximate solution both for problem I and for problem II. In case I the approximation is uniform with respect to  $t$  on the entire interval  $0 \leq t \leq 1$ ; in case II the approximation is not uniform on  $0 \leq t \leq 1$  and loses its meaning in a neighborhood of  $t = 0$ . It is natural to pose the question of constructing a uniform approximation in case II and of constructing approximations of higher order both for case II and for case I.

**2.** Consider the following auxiliary problem with initial conditions. Rewrite (1) in the form of the system

$$\mu \frac{dz}{dt} = -A(t, y)z + B(t, y), \quad \frac{dy}{dt} = z. \quad (6)$$

We shall require that  $A(t, y)$ ,  $B(t, y)$  possess continuous partial derivatives up to and including the second order in the domain  $0 \leq t \leq 1$ ,  $|y| < d$ , and that in this domain the condition  $-A(t, y) < -x < 0$  ( $x = \text{const}$ ) be satisfied. We prescribe for (6) the initial conditions

$$z|_{t=0} = z_0^0, \quad y|_{t=0} = y_0^0 + \mu y_1^0. \quad (7)$$

The results and methods of papers <sup>(2-4)</sup> make it possible to justify the following rule for constructing an asymptotic formula for the solution  $z(t, \mu)$ ,  $y(t, \mu)$  of system (6), under the initial conditions (7), with accuracy  $O(\mu^2)$  on  $0 \leq t \leq 1$ . Introduce a new independent variable  $\tau = t/\mu$ , and rewrite (6) in the form

$$\frac{dz}{d\tau} = -A(\tau\mu, y)z + B(\tau\mu, y), \quad \frac{dy}{d\tau} = \mu z \quad (8)$$

and seek the solution in the form of formal series

$$z = z_0(\tau) + \mu z_1(\tau) + \dots, \quad y = y_0(\tau) + \mu y_1(\tau) + \dots \quad (9)$$

Then

$$\frac{dz_0}{d\tau} = -A(0, y_0)z_0 + B(0, y_0), \quad \frac{dy_0}{d\tau} = 0,$$

$$z_0|_{\tau=0} = z_0^0, \quad y_0|_{\tau=0} = y_0^0; \quad (10')$$

$$\begin{aligned} \frac{dz_1}{d\tau} = & -A(0, y_0)z_1 + [-A_y(0, y_0)z_0 + B_y(0, y_0)]y_1 + \\ & + [-A_t(0, y_0)z_0 + B_t(0, y_0)]\tau, \quad \frac{dy_1}{d\tau} = z_0, \end{aligned} \quad (10'')$$

$$z_1|_{\tau=0} = 0, \quad y_1|_{\tau=0} = y_1^0.$$

Let us write the degenerate system of equations corresponding to (6), i.e. obtained from (6) if one formally sets  $\mu = 0$ :

$$A(t, \bar{y})\bar{z} = B(t, \bar{y}), \quad (11)$$

and consider its solution under the initial condition

$$\bar{y}|_{t=0} = y_0^0. \quad (12)$$

Differentiate (6) with respect to  $\mu$  and again carry out the degeneration. We obtain the system

$$\frac{d}{dt}\bar{z} = -A(t, \bar{y})\bar{z}_\mu + [-A_y(t, \bar{y})\bar{z} + B_y(t, \bar{y})]\bar{y}_\mu, \quad \frac{d}{dt}\bar{y}_\mu = \bar{z}_\mu \quad (13)$$

and find its solution satisfying the initial conditions (4)

$$\bar{y}_\mu|_{t=0} = \bar{y}_\mu(0) = y_1^0 - \int_0^\infty \tau z'_0(\tau) d\tau. \quad (14)$$

Form the expressions

$$Z_0 = \bar{z} + z_0 - \bar{z}(0), \quad Y_0 = \bar{y} + y_0 - \bar{y}(0) = \bar{y} + y_0^0 - y_0^0 = \bar{y}; \quad (15')$$

$$Z_1 = \bar{z} + \mu\bar{z}_\mu + z_0 + \mu z_1 - (\bar{z}(0) + t\bar{z}'(0) + \mu z_\mu(0)),$$

$$Y_1 = \bar{y} + \mu\bar{y}_\mu + \mu y_1 - (t\bar{y}'(0) + \mu\bar{y}_\mu(0)). \quad (15'')$$

Using the methods of <sup>(4)</sup>, one can prove that

$$|z - Z_0| < c\mu, \quad |y - Y_0| < c\mu, \quad (16')$$

$$|z - Z_1| < c\mu^2, \quad |y - Y_1| < c\mu^2, \quad (16'')$$

where  $c$  is a constant independent of  $\mu$  and  $t$  ( $0 \leq t \leq 1$ ), for sufficiently small  $\mu \leq \mu_0$ .

The scheme for obtaining asymptotic formulas can be developed further and approximations of a higher degree of accuracy  $\mu^n$  can be constructed both for the initial conditions (7) and for a broader class

$$z|_{t=0} = z_0^0 + \mu z_1^0 + \dots + \mu^k z_k^0, \quad y|_{t=0} = y_0^0 + \mu y_1^0 + \dots + \mu^k y_k^0.$$

We now prescribe the initial conditions for (6) in the form

$$z|_{t=0} = \frac{z_{-1}^0}{\mu}, \quad y|_{t=1} = y_0^0 \quad (17)$$

and, as in the case (7), we shall construct the solution (8) in the form of formal series

$$z = \frac{z_{-1}(\tau)}{\mu} + z_0(\tau) + \mu z_1(\tau) + \dots, \quad y = y_0(\tau) + \mu y_1(\tau) + \dots \quad (18)$$

Here

$$\frac{dz_{-1}}{d\tau} = -A(0, y_0)z_{-1}, \quad \frac{dy_0}{d\tau} = z_{-1},$$

$$z_{-1}|_{\tau=0} = z_{-1}^0, \quad y_0|_{\tau=0} = y_0^0. \quad (19)$$

We determine the solution  $\bar{z}$ ,  $\bar{y}$  of the degenerate system (11) by the condition\*

$$\bar{y}|_{t=0} = \bar{y}(0) = y_0^0 + \int_0^\infty z_{-1}(\tau) d\tau. \quad (20)$$

By a method analogous to that by which the inequalities (16) were proved, one can prove for the present case that

$$Y_0 = y_0 + \bar{y} - \bar{y}(0) \quad (21)$$

is a uniform approximation to the solution  $y(t, \mu)$  such that

$$|y - Y_0| < c\mu, \quad (22)$$

where  $c$  is a constant independent of  $\mu$  and  $t$  ( $0 \leq t \leq 1$ ), for sufficiently small  $\mu \leq \mu_0$ .

3. The idea of applying the indicated general scheme to the solution of boundary-value problems is as follows: to choose the parameters  $z_{-1}^0$ ,  $y_0^0$ , etc. in the initial conditions (7) or (17) in such a way as to satisfy the prescribed boundary conditions.

Consider boundary-value problem I. Put  $z_0^0 = 0$  in the initial conditions (7). Determine  $y_0^0$  from the requirement  $y_0^0 = \bar{y}|_{t=0}$ , where  $\bar{y}$  is the solution of the degenerate system (11) satisfying the condition  $\bar{y}(1) = 0$  ( $\bar{y}$ , obviously, coincides with  $u$  in (3)), and determine  $y_1^0$  from the requirement

$$y_1^0 - \int_0^\infty \tau z'_0(\tau) d\tau = \bar{y}_\mu|_{t=0},$$

where  $y_\mu$  is the solution of the degenerate system (13) satisfying the condition  $y_\mu|_{t=1} = 0$ . The solution of system (6) obtained with such a choice of parameters in the initial conditions (7) will have the property

$$y|_{t=1} = \left( \bar{y} + \mu \bar{y}_\mu + \frac{\mu^2}{2} \bar{y}_{\mu\mu}^* \right)_{t=1} = \frac{\mu^2}{2} \bar{y}_{\mu\mu}^*|_{t=1} = O(\mu^2), \quad z|_{t=0} = 0.$$

At the same time the solution

---

\*  $\bar{y}(0)$  can also be determined from the equation  $\int_{y_0^0}^{\bar{y}(0)} A(0, y) dy = z_{-1}^0$ .

of boundary-value problem I has the property  $y|_{t=1} = 0$ ,  $z|_{t=0} = 0$ . By the methods of (3) it is not difficult to obtain that the difference between the indicated solution of the problem with initial conditions and the solution of boundary-value problem I is of order  $O(\mu^2)$ , uniformly with respect to  $t$  on the whole interval  $0 \leq t \leq 1$ . And since formulas (15'') constitute, uniformly with accuracy  $O(\mu^2)$ , an approximation to the solution of the problem with initial conditions, the following basic assertion is valid:

The expressions

$$Y_1 = \bar{y} + \mu \bar{y}_\mu + \mu y_1 - t \bar{y}'(0) - \mu \bar{y}_\mu(0),$$

$$Z_1 = \bar{z} + \mu \bar{z}_\mu + z_0 + \mu z_1 - \bar{z}(0) - t \bar{z}'(0) - \mu \bar{z}_\mu(0) \quad (23)$$

(where  $\bar{y}, \bar{z}$  are determined by system (11) and the condition  $\bar{y}|_{t=1} = 0$ ;  $\bar{y}_\mu, \bar{z}_\mu$  are determined by system (13) and the condition  $\bar{y}_\mu|_{t=1} = 0$ ;  $z_0$  is determined by system (10') with initial conditions  $z_0|_{t=0} = 0$ ,  $y_0|_{t=0} = \bar{y}(0)$ ;  $y_1, z_1$  are determined by system (10'') with initial conditions

$$z_1|_{t=0} = 0, \quad y_1|_{t=0} = \bar{y}_\mu(0) + \int_0^\infty \tau z'_0(\tau) d\tau$$

) are, with accuracy  $O(\mu^2)$ , an approximate solution of boundary-value problem I for equation (1) under condition (2'), so that

$$|y(t, \mu) - Y_1| < c\mu^2, \quad |y'(t, \mu) - Z_1| < c\mu^2$$

on the whole interval  $0 \leq t \leq 1$ ;  $c$  is a constant independent of  $\mu$  for sufficiently small  $\mu \leq \mu_0$ .

We note that, prescribing for (6) the initial conditions  $z|_{t=0} = 0$ ,  $y|_{t=0} = y_0^0 + \mu y_0^1 + \dots$ , one can similarly obtain the following approximations for the solution of boundary-value problem I.

Similarly, one can consider boundary-value problem II and assert:

The expression

$$Y_0 = \bar{y} + y_0 - \bar{y}(0) \quad (24)$$

(where  $\bar{y}$  is determined from system (11) with the initial condition  $\bar{y}|_{t=1} = 0$ ;  $y_0$  is determined from (19) with the initial condition

$$z_{-1}|_{t=0} = z_{-1}^0 = \int_0^{\bar{y}(0)} A(0, y) dy, \quad y_0|_{t=0} = 0$$

) is, with accuracy  $O(\mu)$ , an approximate solution of boundary-value problem II for equation (1), so that

$$|y(t, \mu) - Y_0| < c\mu$$

on the whole interval  $0 \leq t \leq 1$ ;  $c$  is a constant independent of  $\mu$  for sufficiently small values  $\mu \leq \mu_0$ .

As in case I, one can develop this scheme and write approximations of higher order.

In conclusion we note that formulas (23), (24) are applicable to the more general boundary-value problem for equation (1)

$$y(0) + \alpha y'(0) = 0, \quad y(1) + \beta y'(1) = 0 \quad (25)$$

with an obvious modification of the initial conditions for the functions entering into (23) in the case  $\alpha \neq 0$ , and into (24) in the case  $\alpha = 0$ .
