## **THE STIELTJES INTEGRAL IN $K$ -SPACES**

*(Presented by Academician V. I. Smirnov on 31 III 1960)*

In a previous paper <sup>(1)</sup> I established the general form of an additive bounded operator in the space of continuous functions with values in a semi-ordered normed space. In the present communication I establish an analogous theorem for the case of functions whose values belong to a semi-ordered space in which the existence of a real norm is not postulated. Whereas in the paper mentioned continuity was understood with respect to the norm, below we shall consider functions continuous with respect to order.

**1. Stieltjes integrals.** Let  $X$  be a  $K$ -space\* and let  $T = [a, b]$  be a segment of the real axis. We shall consider functions defined on  $T$  whose values belong to  $X$ . If such a function is bounded, then we denote

$$v(\delta) = \sup_{|t_1 - t_2| < \delta} |f(t_1) - f(t_2)|.$$

The function  $f$  is uniformly continuous (see also <sup>(3,4)</sup>) if

$$(o)\text{-}\lim_{\delta \rightarrow 0} v(\delta) = 0.$$

A function  $g$ , defined on  $T$  with values in a  $K$ -space  $Z$ , is of bounded variation on  $T$  if the set of all elements of the form  $\sum_i |g(t_{i+1}) - g(t_i)|$ , corresponding to all partitions of the segment  $T$ , is bounded. We denote by

$$\text{var}_{t \in T} g(t)$$

or by  $W_g$  the least upper bound of this set.

Let  $Y$  also be a  $K$ -space and let  $(X, Y)_o^r$  be the space of regular and  $(o)$ -continuous operators defined on  $X$  and with values in  $Y$ . In what follows we suppose that  $Z = (X, Y)_o^r$ .

Now let  $f$  be a uniformly  $(o)$ -continuous function on  $T$  with values in  $X$ , and let  $g$  be a function of bounded variation on  $T$  with values in  $Z$ . For any partition  $\Delta$  of the segment  $T$ ,

$$a = t_0 < t_1 < \dots < t_{\lambda-1} < t_\lambda = b,$$

we form the “Stieltjes-Riemann sum”

$$s = \sum_{i=0}^{\lambda-1} [g(t_{i+1}) - g(t_i)](f(\theta_i)), \quad (1)$$

where the “intermediate points”  $\theta_i \in [t_i, t_{i+1}]$  are arbitrary.

We denote by  $\delta$  the number equal to the greatest of the lengths of the partial segments in the partition  $\Delta$ .

Let  $\{\Delta_\nu\}$  be a sequence of partitions of the segment  $T$  such that  $\delta_\nu \rightarrow 0$ . For each  $\nu$  denote by  $s_\nu$  the sum of the form (1) constructed for the partition  $\Delta_\nu$ . If for all  $\nu$  the partition  $\Delta_{\nu+1}$  is a refinement

---

\* With some exceptions we shall use the notation of (2).

of the partition  $\Delta_\nu$ , one may verify that

$$|s_\nu - s_{\nu+\mu}| \leq W_g(v(\delta_\nu)) \quad (\nu, \mu = 1, 2, \dots). \quad (2)$$

Since  $W_g \in (X, Y)_o^r$ , and  $v(\delta_\nu) \rightarrow 0$ , it follows from (2) that there exists  $s = (o)\text{-}\lim_\nu s_\nu$ .

Then, as in the case of real functions, one may verify that for any sequence of partitions  $\{\Delta'_\nu\}$  such that  $\delta'_\nu \rightarrow 0$ , and for any intermediate points used in the sums  $s'_\nu$ , there exists  $(o)\text{-}\lim_\nu s'_\nu$ , and it is equal to  $s$ . We call the element  $s$  the **integral of the function  $f$  with respect to the function  $g$**  and denote it by  $\int_T dg(t) f(t)$ .

It is easy to verify the usual properties:

$$\int_T dg(t) [f_1(t) + f_2(t)] = \int_T dg(t) (f_1(t)) + \int_T dg(t) (f_2(t)), \quad (3)$$

$$\int_T dg(t) [\lambda f(t)] = \lambda \int_T dg(t) f(t), \quad (4)$$

and also the relation

$$\left| \int_T dg(t) (f(t)) \right| \leq W_g \left( \sup_{t \in T} |f(t)| \right). \quad (5)$$

**2. Additive bounded operators.** Denote by  $M(T, X)$  the set of all bounded functions defined on the segment  $T$ , whose values belong to  $X$ . In this set we define, as usual, addition of elements and multiplication by numbers, and introduce the norm

$$|f| = \sup_{t \in T} |f(t)|$$

with values in  $X$ . It is not difficult to verify that  $M(T, X)$  is a  $B_K$ -space <sup>(2)</sup>. The subspace  $C(T, X)$  of all uniformly continuous functions is also a  $B_K$ -space.

If  $f_1, f_2 \in M(T, X)$ , then we put  $f_1 \leq f_2$  if  $f_1(t) \leq f_2(t)$  for all  $t \in T$ . Then  $M(T, X)$  and  $C(T, X)$  are  $K$ -linear <sup>(2)</sup>, and the modulus of an element  $f \in C(T, X)$  coincides with the modulus of the same element computed in  $M(T, X)$ .

It is clear that

$$|f_1| \leq |f_2| \Rightarrow |f_1| \leq |f_2|.$$

If  $\mathcal{V}$  is a space of type  $(B_K)$ , normed by means of  $X$ , and  $U$  is an additive operator mapping  $\mathcal{V}$  into a  $K$ -space  $Y$ , then we say that  $U$  is a **bounded operator** if there exists a positive operator  $V \in (X, Y)_o^r$  such that

$$|U(f)| \leq V|f| \tag{6}$$

for all  $f \in \mathcal{V}$ .

In this case there exists a least operator  $V$ —the norm\* of the operator  $U$ , denoted by  $|U|$ .

If  $\mathcal{V} = C(T, X)$ , then one may verify that\*\* an additive operator  $U$  is bounded if and only if  $U$  is regular, and  $|U|$  is  $(oo)$ -continuous on  $X$ . In this case  $|U| = |U|$  on  $X$ .

\* See <sup>(2)</sup>, Ch. XII, 1.34. From  $0 \leq |U| \leq V$  and  $V \in (X, Y)_o^r$  it follows that  $|U| \in (X, Y)_o^r$ .

\*\* We identify the set of constant functions in  $C(T, X)$  with the set  $X$ .

For each  $f \in C(T, X)$  denote

$$I(f) = \int_T dg(t)(f(t)),$$

where  $g$  is some function of bounded variation on  $T$  with values in  $(X, Y)_o^r$ .

From (3), (5) it follows that the operator  $I$  is additive and bounded, and

$$|I| \leq \operatorname{var}_{t \in T} g(t). \quad (7)$$

Let us now consider an arbitrary additive and bounded operator  $U$  on  $C(T, X)$  with values in  $Y$ . We have

$$|U(f)| \leq |U|(|f|),$$

where  $|U| \in (X, Y)_o^r$ . The operator  $U$  can be extended to  $M(T, X)$  with preservation of additivity and norm (see <sup>(2)</sup>, Ch. IX, 1.11). We shall denote the extended operator by the same letter.

For each  $t \in T$  denote by  $g(t)$  the operator from  $X$  into  $Y$  defined by the equality

$$g(t)(x) = U(\gamma_t x),$$

where, for  $t \neq a$ ,  $\gamma_t$  is the characteristic function of the segment  $[a, t]$ , and  $\gamma_a = 0$ ;  $\gamma_t x$  is the function  $(\gamma_t x)(\tau) = \gamma_t(\tau)(x)$ . It is easy to see that for every  $t \in T$  the operator  $g(t)$  is regular and  $(oo)$ -continuous.

Since for all  $x \geq 0$  ( $x \in X$ ) and for any partition  $\Delta$  of the segment  $T$

$$\left\{ \sum_i |g(t_{i+1}) - g(t_i)| \right\} (x) \leq |U|(x),$$

it follows that  $g$ , as a function on  $T$  with values in  $(X, Y)_o^r$ , is of bounded variation and

$$\operatorname{var}_{t \in T} g(t) \leq |U|. \quad (8)$$

Let now  $f \in C(T, X)$ , and let  $\Delta$  be an arbitrary partition of the interval  $T$ . In the notation of Section 1 we have

$$\sup_{t', t'' \in [t_i, t_{i+1}]} |f(t') - f(t'')| \leq v(\delta).$$

Put

$$h(t) = \begin{cases} f(t_0), & \text{for } a \leq t \leq t_1, \\ f(t_i), & \text{for } t_i < t \leq t_{i+1} \quad (i \geq 1). \end{cases}$$

It is clear that  $h \in M(T, X)$  and

$$|f - h| \leq v(\delta),$$

whence it follows that

$$|U(f) - U(h)| \leq |U|(v(\delta)).$$

On the other hand,

$$h = \sum_i (\gamma_{t_{i+1}} - \gamma_{t_i}) f(t_i),$$

and, consequently,

$$U(h) = \sum_i [g(t_{i+1}) - g(t_i)](f(t_i)).$$

Hence we conclude that

$$U(f) = \int_T dg(t)(f(t)). \quad (9)$$

From (7) and (8) it also follows that

$$|U| = \operatorname{var}_{t \in T} g(t). \quad (10)$$

We have obtained the following result:

**Theorem.** *The general form of an additive bounded operator transforming  $C(T; X)$  into  $Y$  is given by formula (9), where  $g$  is a function of bounded variation with values in  $(X, Y)_o^r$ . In this case the function  $g$  can be chosen so that the equality (10) is satisfied.*

**Remarks.** 1°. If  $X$  is a regular  $K$ -space, and  $U$  is a regular operator on  $C(T, X)$ , then  $U$  is bounded. This assertion is obvious.

2°. Let  $Y = X$ , and let  $X$  be a  $K^+$ -space with unit  $(^2)$ . For  $x \in X$  and  $f \in C(T, X)$ , denote by  $x \cdot f$  the function  $(x \cdot f)(t) = x \cdot f(t)$ , if for every  $t \in T$  the Boolean product  $x \cdot f(t)$  exists and  $\sup_{t \in T} |x \cdot f(t)| < \infty$ .

Let  $U$  be an additive operator from  $C(T, X)$  into  $X$  such that, if  $x \cdot f$  exists, then

$$U(x \cdot f) = x \cdot U(f) \quad (x \in X; f \in C(T, X));$$

we also assume that  $U(f_\nu) \xrightarrow{o} 0$  if  $|f_\nu| \xrightarrow{o} 0$ . In this case  $U$  is bounded (see <sup>(4)</sup>, theorem 2), and we obtain Vulik' s result (see <sup>(4)</sup>, theorem 3).

3°. In the case when  $X$  is the real axis, and  $Y$  is a  $K^+$ -space of countable type, we obtain Kantorovich' s theorem (see <sup>(2)</sup>, Ch. VIII, 4.11).
