# ON THE EIGENFUNCTIONS OF A CERTAIN INTEGRAL EQUATION

*(Presented by Academician I. N. Vekua, 19 VIII 1959)*

I. N. Vekua <sup>(1)</sup> constructed a theory of solutions of the elliptic system of differential equations

$$U_{\bar{z}} = |AU_* + \overline{B\bar{U}} + C_* \quad (1)$$

An important place in the construction of this theory was occupied by the proof of the fact that the equation

$$U(z) + \frac{1}{\pi} \iint_T \frac{B(t)\overline{U(t)}}{t-z} dT = 0 \quad (2)$$

has no nontrivial solutions.

In constructing the theory of generalized analytic functions on Riemann surfaces, consideration of a certain integral equation analogous to (2) is of great significance. The present note contains an example of such an equation having eigenfunctions.

Let the contour  $\Gamma$  bound, on a closed Riemann surface  $R$  of genus  $p$ , a domain  $T$ . Let  $A(\zeta, z)$  be an elementary function of the first kind of the domain  $T$ , covariant in  $\zeta$ , invariant in  $z$ , analytic in both variables and having in  $T$  a single pole of the first order with residue  $+1$  at the point  $P[\zeta] = P[z]$ . One of the possible constructions of such a function is given in <sup>(2)</sup>.

For what follows, the behavior of  $A(\zeta, z)$  in the cylindrical domain  $(R - T)_\zeta \times (R - T)_z$  is important. In this domain  $A(\zeta, z)$  has a pole of the first order with residue  $-1$  at the point  $P[\zeta] = P_0$ , provided that  $P[z] \neq P_0$ . At the point  $P[\zeta] = P[z] = P_0$ , the function  $A(\zeta, z)$  is regular. There are poles of the first order at the points  $P[z] = P_\mu$  ( $\mu = 1, 2, \dots, p$ ), provided that  $P[\zeta] \neq P_\mu$  ( $\mu = 1, 2, \dots, p$ ).<sup>\*</sup> In the case  $P[z] = P[\zeta] = P_\mu$ , the function  $A(\zeta, z)$  is regular. There is a pole of the first order with residue  $+1$  at the point  $P[\zeta] = P[z] \neq P_\nu$ , ( $\nu = 0, 1, \dots, p$ ). In addition, we shall assume that, for  $P[z_0] = P_0$ ,  $A(\zeta, z_0) \equiv 0$ . For this purpose it is enough to subtract from the function constructed in <sup>(2)</sup> the covariant of the first kind  $A(\zeta, z_0)$ . The point  $P_0$  is chosen arbitrarily in

$R - T$ . The points  $P_\mu$  ( $\mu = 1, 2, \dots, p$ ) are also chosen with a large degree of arbitrariness, more precisely:

**Theorem 1.** *In order that a system of points be able to be the set of singularities (in  $z$ ) of the function  $A(\zeta, z)$ , it is necessary and sufficient that there not exist a covariant of the first kind  $Z'(z)$  vanishing at all these points.*

\* In (2) it is proved that the number of these points does not exceed  $p$ . The fact that there are exactly  $p$  of them was proved by S. Ya. Gusman. This will, in particular, follow from Theorem 1.

**Proof. Necessity of the condition\***. Let there exist a covariant  $Z'(z)$  having zeros at the indicated points. Then the product  $A(\zeta, z)Z'(z)$  is a covariant in  $z$ , having a single pole at  $z = \zeta$ . Hence it follows that  $Z'(z) \equiv 0$ .

In particular, there cannot be fewer than  $p$  such points, since for any  $p - 1$  points there exists a covariant possessing the indicated property (4).

**Sufficiency of the condition** follows from the properties of this set of points (2). The indicated points form a divisor  $\Delta$  (3). Obviously,  $\text{ord } \Delta = p$ ,  $\dim(W/\Delta) = 0$ . Therefore, by the Riemann-Roch theorem,  $\dim \Delta = 1$ , i.e. on  $R$  there exists no rational function having poles only at the points of  $\Delta$ .

Consider the system of differential equations in  $T$

$$U_{\bar{z}} = B(z)\bar{U}, \quad (3)$$

where the coefficient depends on the local parameter as follows:

$$B^*(z^*) = B(z)\frac{d\bar{z}}{dz^*},$$

where  $z$  and  $z^*$  are local parameters. For constructing the theory of this equation, the basic role is played by the equation

$$U(z) + \frac{1}{\pi} \iint_T B(t)\overline{U(t)} A(t, z) dT = 0. \quad (4)$$

**Theorem 2.** *If there exists a solution  $U_0(z)$ , regular in  $T$ , of equation (3), analytically continuable into  $R - T$  in such a way that in this domain it is a multiple of the divisor  $1/\Delta$  and has a zero at the point  $P_0$ , then equation (4) is solvable.*

Consider the function

$$H(z) \equiv U_0(z) + \frac{1}{\pi} \iint_T B(t)\overline{U_0(t)} A(t, z) dT. \quad (5)$$

Obviously, this is a function analytic on  $R$ , a multiple of the divisor  $1/\Delta$ . In view of the fact that  $\dim \Delta = 1$ ,  $H(z) \equiv \text{const}$ . At the point  $P_0$  the right-hand side of (5) vanishes; therefore  $H(z) \equiv 0$ . Consequently,  $U_0(z)$  is an eigenfunction of equation (4),  $\lambda = 1/\pi$ . It remains to construct a function satisfying the requirements of Theorem 2.

In the domain  $T$  consider the system

$$W_{\bar{z}} = D(z)w, \quad (6)$$

where  $D^*(z^*) = D(z) d\bar{z}/dz^*$ . We shall construct a solution  $W_0$ , regular in  $T$ , of this system, analytically continuable into  $R - T$  as in Theorem 2. The function  $W_0(z)$  satisfies the system

$$W_{0\bar{z}} = \tilde{B}(z)\overline{W_0}, \quad (6')$$

where

$$\tilde{B}(z) = D(z)W_0(z)/\overline{W_0(z)}.$$

Thus, the construction of the required example is reduced to the construction of a function  $W_0(z)$ , for which we use the theory of the Riemann problem<sup>(5,6)</sup>. Put  $T^+ = T$  and  $T^- = R - T - \Gamma$ . The function  $W_0(z)$  has in  $T^+$  the representation

$$W_0(z) = \varphi^+(z) \exp \omega(z),$$

where  $\varphi^+(z)$  is regular analytic in  $T^+$ , and

$$\omega(z) = -\frac{1}{\pi} \iint_T D(t) A(t, z) dt.$$

In  $T^-$  the desired function has the representation  $W_0(z) = \varphi^-(z)/\Delta(z)$ , where  $\varphi^-(z)$  is a regular analytic function in  $T^-$  and  $\Delta(z)$  is a regular analytic

---

\* The proof of necessity given here is due to S. Ya. Gusman.

into a  $T^-$ -function whose zeros are determined by the divisor  $\Delta$ . We arrive on  $\Gamma$  at the problem

$$\varphi^+(t) = \frac{e^{-\omega(t)}}{\Delta(t)} \varphi^-(t). \quad (7)$$

The index of this problem is equal to  $p$ ; consequently, by (6), this problem is solvable.

In order to normalize the solution at the point  $P_0$ , it is sufficient to have at least two linearly independent solutions. Problem (7) has no more than  $p + 1$  solutions<sup>(5)</sup>. Let  $G(t)$  be a function of index  $p$  such that the problem  $\psi^+(t) = G(t)\psi^-(t)$  has exactly  $p + 1$  solutions. Its existence follows from the results of work<sup>(5)</sup>.

In order that problem (7) have the same number of solutions, it is sufficient<sup>(5)</sup> that

$$\int_{\Gamma} \ln[G(t)\Delta(t)e^{\omega(t)}] dZ_k(t) = 0 \quad (k = 1, 2, \dots, p), \quad (8)$$

where  $dZ_k$  ( $k = 1, 2, \dots, p$ ) is a basis of differentials of the first kind on the surface  $R$ . We obtain

$$\int_{\Gamma} \omega(t) dZ_k = - \int_{\Gamma} \ln G(t)\Delta(t) dZ_k. \quad (9)$$

By a simple calculation we verify that

$$\int_{\Gamma} \omega(t) dZ_k = 2i \iint_{T^+} D(t)Z'_k(t) dT \quad (k = 1, \dots, p). \quad (10)$$

Choosing  $D(z)$  so that condition (8) is satisfied, we obtain that problem (7) has  $p + 1$  solutions, which makes it possible, for  $p > 1$ , to obtain the required normalization.

The author expresses his deep gratitude to his scientific adviser, Prof. L. I. Volkovskii.
