## REPRESENTATIONS OF THE GROUP $Z_2 \times Z_2$ OVER A FIELD OF CHARACTERISTIC 2 \*

*(Presented by Academician I. M. Vinogradov on 15 III 1961)*

O. Higman <sup>(2)</sup> showed that if a Sylow  $p$ -subgroup of a finite group  $G$  is not cyclic, then the group  $G$  has infinitely many inequivalent indecomposable representations by matrices with entries from a field  $k$  of characteristic  $p$ . However, the problem of a complete description of all representations is still far from being solved. Even in the simplest situation, when  $G = Z_2 \times Z_2$  and the field  $k$  has characteristic 2, as far as we know, not all representations have been found.

In Section 1 of this paper all indecomposable representations of the group  $Z_2 \times Z_2$  over an algebraically closed field  $k$  of characteristic 2 are found. Further, the set of equivalence classes of representations of a group  $G$  over a field  $k$  forms an associative semiring: addition is induced by the direct sum of representations  $\oplus$ , and multiplication by the tensor product of representations  $\otimes$ . The minimal ring  $\mathfrak{A}$  containing this semiring is called the **representation ring** of the group  $G$  over the field  $k$ .

In Section 2 the structure of this ring is studied for  $G = Z_2 \times Z_2$ . In particular, it turns out that this ring has an infinite number of generators.

1. Let  $G$  be a  $p$ -group,  $\mathfrak{D} = k[G]$  the group algebra of the group  $G$  over a field  $k$  of characteristic  $p$ ;  $I$  the ideal of the algebra  $\mathfrak{D}$  consisting of elements of the form  $\sum_{\sigma \in G} \alpha_\sigma \sigma$ , where  $\sum_{\sigma \in G} \alpha_\sigma = 0$ . The  $\mathfrak{D}$ -module  $I$  is a free  $k$ -module of rank  $p^s - 1$  ( $p^s = \text{ord } G$ ). Let  $S$  be the ideal consisting of elements  $\gamma \sum_{\sigma \in G} \sigma$ ,  $\gamma \in k$ . As a  $\mathfrak{D}$ -module the ideal  $S$  is isomorphic to the  $\mathfrak{D}$ -module  $k$ , on which the elements of  $G$  act trivially. The quotient module  $J = \mathfrak{D}/S$  is a free  $k$ -module of rank  $p^s - 1$ . Denote by  $\text{Sp}$  the mapping

$$a \mapsto \sum_{\sigma \in G} \sigma a, \quad a \in A.$$

**Lemma 1.** *If  $A$  is an indecomposable  $\mathfrak{D}$ -module distinct from  $\mathfrak{D}$ , then  $\text{Sp}(A) = (0)$ .*

The proof of this lemma is given in <sup>(1)</sup>.

**Remark 1.** It is clear that all unitary  $\mathfrak{D}$ -modules are essentially  $I$ -modules, since any  $I$ -module can be made into a  $\mathfrak{D}$ -module by putting  $e \cdot a = a$ , where  $e$  is the identity of the group  $G$  and  $a \in A$ . If  $\text{Sp}(A) = (0)$ , then the  $I$ -module is in fact an  $N$ -module, where  $N = I/S$ . Therefore, by Lemma 1, all indecomposable

$\mathfrak{D}$ -modules distinct from  $\mathfrak{D}$  are  $N$ -modules. In the language of representation theory this means that the problem of finding all indecomposable representations of the group  $G$  is equivalent to the problem of finding all representations of the algebra  $N$ .

If now  $G = Z_2 \times Z_2$ ,  $\sigma, \tau$  are its generators and the field  $k$  has characteristic 2, then the ideal  $I$  is generated by the elements  $\sigma - e, \tau - e$ , where  $e$  is the identity of the group  $G$ , and  $S = I^2$ . Therefore  $N = I/I^2$  is an algebra with two generators  $\nu_1$  and  $\nu_2$  and zero multiplication. Denote by  $A'$  the submodule of the module  $A$  consisting of all elements  $a \in A$  such that  $\nu \cdot a = 0$  ( $\nu \in N$ ), and let  $A'' = A/A'$ . Then for elements  $a'' \in A''$  we have  $\nu \cdot a'' = 0$  ( $\nu \in N$ ).

**Lemma 2.** *If  $A$  and  $B$  are two  $N$ -isomorphic  $N$ -modules, then an  $N$ -isomorphism  $A \xrightarrow{\varphi} B$  induces an  $N$ -isomorphism  $A' \xrightarrow{\varphi'} B'$ .*

\* The results of this work were reported at the seminar on algebraic geometry and homological algebra in Uzhgorod in October 1959.

The proof of Lemma 2 is obvious.

The considerations carried out above in the language of module theory show that, in a suitable basis, every representation of the algebra  $N$  has the form

$$v_i \rightarrow \begin{pmatrix} 0_{nn} & A_{nm}^{(i)} \\ 0_{mn} & 0_{mm} \end{pmatrix}, \quad i = 1, 2, \quad (1)$$

where  $A_{nm}^{(i)}$  ( $i = 1, 2$ ) are rectangular  $(n, m)$ -matrices having no common annihilating vectors;  $0_{nn}, 0_{mn}, 0_{mm}$  are zero matrices; moreover, by Lemma 2, different bases in which the representation has the form (1) are connected by a linear transformation with matrix

$$Q = \begin{pmatrix} P_{nn} & * \\ 0_{mn} & P_{mm} \end{pmatrix},$$

where  $P_{nn}, P_{mm}$  are nonsingular square matrices, and  $0_{mn}$  is the zero matrix. Therefore equivalent representations of type (1) have the form

$$v_i \rightarrow \begin{pmatrix} 0_{nn} & P_{nn}^{-1} A_{nm}^{(i)} P_{mm} \\ 0_{nm} & 0_{nn} \end{pmatrix}, \quad i = 1, 2.$$

Thus, every representation of the algebra  $N$  is determined by a pair of rectangular matrices  $A_{nm}^{(i)}$  ( $i = 1, 2$ ) having no common annihilating vector, and equivalent representations are determined by a pair of matrices  $A'_{nm}{}^{(i)}$  ( $i = 1, 2$ ) such that  $A'_{nm}{}^{(i)} = P_{nn}^{-1} A_{nm}^{(i)} P_{mm}$ . The pair of matrices  $A'_{nm}{}^{(i)}$  ( $i = 1, 2$ ) is called **strictly equivalent** to the pair of matrices  $A_{nm}^{(i)}$  ( $i = 1, 2$ ).

Thus, the problem of finding all representations of the algebra  $N$  is reduced to the problem of reducing a pair of matrices  $A_{nm}^{(i)}$  ( $i = 1, 2$ ), or, what is the same thing, the pencil of matrices  $A_{nm} = A_{nm}^{(2)} + \lambda A_{nm}^{(1)}$ , to a strictly equivalent canonical form. Since the pair of matrices  $A_{nm}^{(i)}$  ( $i = 1, 2$ ) has no common annihilating vector, there is no linear dependence with constant coefficients among the rows of the pencil  $A_{nm}$ . Such a pencil (3) is strictly equivalent to a pencil of the form:

$$(0_{ng}, A_{n,m-g}^{(2)}) + \lambda(0_{ng}, A_{n,m-g}^{(1)}), \quad (2)$$

where the pencil  $A_{n,m-g} = A_{n,m-g}^{(2)} + \lambda A_{n,m-g}^{(1)}$  has the quasidiagonal form

$$A_{n,m-g} = \{L_{\varepsilon_1}, \dots, L_{\varepsilon_r}; L'_{\eta_1}, \dots, L'_{\eta_s}; N^{(1)}, \dots, N^{(t)}, J_1 + \lambda E_1, \dots, J_u + \lambda E_u\}.$$

Here

$$L_{\varepsilon_i} = \left( \begin{array}{ccccccc} \lambda & 1 & 0 & \dots & \dots & 0 & \\ 0 & \lambda & 1 & 0 & \dots & \dots & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \\ 0 & \cdot & \cdot & \cdot & \lambda & 1 & 0 \\ 0 & 0 & \cdot & \cdot & 0 & \lambda & 1 \end{array} \right) \varepsilon_i,$$

$$L'_{\eta_i} = \left( \begin{array}{ccccccc} \lambda & 0 & 0 & \dots & \dots & 0 & \\ 1 & \lambda & 0 & \dots & \dots & \cdot & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \\ \cdot & \cdot & \cdot & \cdot & \lambda & 0 & \\ 0 & \cdot & \cdot & 1 & \lambda & & \\ 0 & 0 & \cdot & \cdot & 0 & 1 & \end{array} \right) \eta_i + 1,$$

$$N^{(i)} = \left( \begin{array}{ccccccc} 1 & \lambda & 0 & \dots & \dots & 0 & \\ 0 & 1 & \lambda & \dots & \dots & \cdot & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \\ \cdot & \cdot & \cdot & \cdot & \lambda & 0 & \\ 0 & \cdot & \cdot & 1 & \lambda & & \\ 0 & 0 & \cdot & \cdot & 0 & 1 & \end{array} \right) \nu_i,$$

$$J_i = \left( \begin{array}{ccccccc} \lambda_i & 1 & 0 & \dots & \dots & 0 & \\ 0 & \lambda_i & 1 & \dots & \dots & \cdot & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \\ \cdot & \cdot & \cdot & \cdot & \cdot & 0 & \\ 0 & \cdot & \cdot & \lambda_i & 1 & & \\ 0 & 0 & \cdot & \cdot & 0 & \lambda_i & \end{array} \right) \mu_i.$$

At the same time it is assumed that the entries of the matrices of the pencil  $A_{nm}$  lie in the algebraically closed field  $k$ .

We shall call a pencil  $A$ , among whose rows there is no linear dependence with constant coefficients, **decomposable** if it is strictly equivalent to a pencil of the form (2) or to a pencil of quasidiagonal form  $\{A_1, A_2\}$ . The representation (1) of the algebra  $N$  corresponding to the pencil  $A$  will be denoted by  $d(A)$ .

**Lemma 3.** The representation  $d(A)$  is decomposable if and only if the corresponding pencil  $A$  is decomposable.

The proof of this lemma presents no difficulties.

It remains to note that from the uniqueness of the canonical form of a pencil and from Lemma 3 it follows that the representations  $d(L_{\varepsilon_i})$ ,  $d(L'_{\eta_i})$ ,  $d(N^{(i)})$ ,  $d(J_i + \lambda E_i)$  of the algebra  $N$  are indecomposable and that, together with the zero representation, they exhaust all indecomposable representations of the algebra  $N$ . Therefore, taking Remark 1 into account, the following may be regarded as proved:

**Proposition 1.** All indecomposable nonequivalent representations of the group  $Z_2 \times Z_2$  over an algebraically closed field  $k$  of characteristic 2 are exhausted by the following representations:

- 1) The unit representation

$$\varepsilon(\sigma) = 1, \quad \varepsilon(\tau) = 1.$$

- 2) Representations of order  $2s + 1$ ,  $s = 1, 2, \dots$ ,

$$I_{2s+1}(\sigma) = \begin{pmatrix} E_{s+1} & L'_s(0) + L'_s(1) \\ & E_s \end{pmatrix}, \quad I_{2s+1}(\tau) = \begin{pmatrix} E_{s+1} & L'_s(0) \\ & E_s \end{pmatrix}.$$

$$J_{2s+1}(\sigma) = \begin{pmatrix} E_s & L_s(0) + L_s(1) \\ & E_{s+1} \end{pmatrix}, \quad J_{2s+1}(\tau) = \begin{pmatrix} E_s & L_s(0) \\ & E_{s+1} \end{pmatrix}.$$

- 3) Representations of order  $2s$ ,  $s = 1, 2, \dots$ ,

$$\Delta_{2s}(\lambda)(\sigma) = \begin{pmatrix} E_s & E_s \\ & E_s \end{pmatrix}, \quad \Delta_{2s}(\lambda)(\tau) = \begin{pmatrix} E_s & J_s(\lambda) \\ & E_s \end{pmatrix}, \quad \lambda \in k, \quad s = 1, 2, \dots,$$

$$\Delta_{2s}(\infty)(\sigma) = \begin{pmatrix} E_s & J_s(0) \\ & E_s \end{pmatrix}, \quad \Delta_{2s}(\infty)(\tau) = \begin{pmatrix} E_s & E_s \\ & E_s \end{pmatrix}.$$

- 4) The regular representation  $R$  of order 4.

2. As before,  $G = Z_2 \times Z_2$ ;  $k$  is a field of characteristic 2. The  $k$ -module  $I$  in this case is a free  $k$ -module of rank 3. The representation of dimension 3 of the group  $G$  corresponding to this module will also be denoted by  $I$ .  $J$  is also a free  $k$ -module of rank 3. The corresponding representation of dimension 3 will likewise be denoted by  $J$ .

**Remark 2.** One can verify that the representation  $I$  is equivalent to the representation  $I_3$ , and the representation  $J$  is equivalent to the representation  $J_3$ , obtained by us in Proposition 1. In [1] it is proved that the representation  $I$  is dual to the representation  $J$ . It turns out that the representation  $I_{2s+1}$  is also dual to the representation  $J_{2s+1}$ . Obviously,  $R$  is dual to itself.

In the subsequent computations the following will be useful.

**Lemma 4.** Let  $G$  be a  $p$ -group, and let  $k$  be a field of characteristic  $p$ . Then the regular representation  $R$  of the group  $G$  is contained as a direct summand in a representation  $D$  as many times as the rank of the matrix

$$\text{Sp } D = \sum_{\sigma \in G} D(\sigma).$$

This lemma is easily proved with the aid of Lemma 1.

Let us now proceed to the computation of the representation ring  $\mathfrak{A}$  of the group  $G$ . Obviously,  $\varepsilon$  is the identity of this ring. Moreover, it is known that

$$D \otimes R = \underbrace{R \oplus \dots \oplus R}_{m \text{ times}} = mR,$$

where  $m$  is the dimension of the representation  $D$ .

**Proposition 2.**

$$\begin{aligned} I_{2s+1} \otimes I_{2t+1} &= I_{2(s+t)+1} \oplus stR, \\ J_{2s+1} \otimes J_{2t+1} &= J_{2(s+t)+1} \oplus stR, \\ I_{2s+1} \otimes J_{2t+1} &= I_{2(s-t)+1} \oplus (st+t)R, \quad \text{if } s > t. \\ I_{2s+1} \otimes J_{2s+1} &= \varepsilon \oplus (s^2 + s)R, \\ I_{2s+1} \otimes J_{2t+1} &= J_{2(t-s)+1} \oplus (st+s)R, \quad \text{if } s < t. \end{aligned}$$

The **proof** is based on Lemma 4, Proposition 1, and the results of [1].

**Lemma 5.**

$$\Delta_{2n}(\lambda) \otimes \Delta_{2m}(\mu) = nmR, \quad \text{if } \lambda \neq \mu,$$

$$\Delta_{2n}(\lambda) \otimes \Delta_{2m}(\lambda) = (nm - \min(m, n))R \oplus D_{4\min(m, n)},$$

where  $D_{4\min(m, n)}$  is a representation of the group  $G$  of dimension  $4\min(m, n)$ , not containing  $R$ .

This lemma is easily proved with the aid of Lemma 4.

**Proposition 3.**

$$I_{2s+1} \otimes \Delta_{2t}(\lambda) = \Delta_{2t}(\lambda) \oplus stR,$$

$$J_{2s+1} \otimes \Delta_{2t}(\lambda) = \Delta_{2t}(\lambda) \oplus stR.$$

The **proof** is based on Lemmas 4, 5, Propositions 1, 2, and the results of [1].

The following lemma, which we shall state without proof, will be needed later.

**Lemma 6.** Let  $\mathfrak{A}$  be an associative, commutative ring with generators  $x_s$  ( $s = 1, 2, \dots; x_0 = 0$ ), on which an integer-valued linear functional  $f$  is defined such that  $f(x_s) = s$ ,  $f(x_s \cdot x_t) = 2 \min(s, t)$ . Then  $x_m \cdot x_n = 2x_{\min(m, n)}$ , if  $m \neq n$ .

**Proposition 4.**

$$\Delta_{2n}(\lambda) \otimes \Delta_{2m}(\mu) = nmR, \quad \lambda \neq \mu. \quad (3)$$

For  $\lambda \neq 0, 1, \infty$ :

$$\Delta_{2n}(\lambda) \otimes \Delta_{2m}(\lambda) = (nm - \min(m, n))R \oplus 2\Delta_{2\min(m, n)}(\lambda), \quad m \neq n; \quad (4)$$

$$\Delta_{2n}(\lambda) \otimes \Delta_{2n}(\lambda) = \begin{cases} (n^2 - n)R \oplus 2\Delta_{2n}(\lambda), & n \equiv 0 \pmod{2}, \\ (n^2 - n)R \oplus \Delta_{2(n-1)} \oplus \Delta_{2(n+1)}, & n \equiv 1 \pmod{2}; \end{cases} \quad (5)$$

For  $\lambda = 0, 1, \infty$ :

$$\Delta_{2n}(\lambda) \otimes \Delta_{2m}(\lambda) = (nm - \min(m, n))R \oplus 2\Delta_{2\min(m, n)}(\lambda). \quad (6)$$

**Proof.** Formula (3) was established by us in Lemma 5. It was also established there that  $R$  is contained in  $\Delta_{2n}(\lambda) \otimes \Delta_{2m}(\lambda)$  exactly  $(nm - \min(n, m))$  times. Let  $\mathfrak{A}$  be the representation ring of the group  $G$ ,  $W$  the ideal generated by the regular representation  $R$ , and  $\mathfrak{A}^* = \mathfrak{A}/W$ . Using the results of Proposition 3 and Lemma 5, we find that, for fixed  $\lambda$ , the linear subspace  $\mathfrak{B}_\lambda^*$ , generated by the classes  $x_s = \{\Delta_{2s}(\lambda) \bmod W\}$ , forms a subring of the ring  $\mathfrak{A}^*$ . Define on this ring an integer-valued linear functional  $f$ , putting  $f(x_s) = s$ . According to Lemma 5,  $f(x_s \cdot x_t) = 2 \min(s, t)$ ,  $s \neq t$ . To obtain (4), it remains to apply Lemma 6 to the ring  $\mathfrak{B}_\lambda^*$ . For the proof of relations (5) and (6) it is necessary to carry out rather lengthy computations, essentially using the structure of the representations  $\Delta_{2s}(\lambda)$ . We omit these computations. This completes the proof of Proposition 4.

It remains to say that Propositions 2, 3, and 4 completely determine the structure of the ring  $\mathfrak{A}$ . In particular, it is clear that this ring has no finite number of generators.

The present work was carried out under the supervision of I. R. Shafarevich, to whom the author expresses sincere gratitude.
