### **ON THE ABSENCE OF POLYHEDRAL SPECTRA FOR BICOMPACTA**

*(Presented by Academician P. S. Aleksandrov, 14 IX 1961)*

Freudenthal proved <sup>(1)</sup> that every compactum  $\Phi$  can be represented as the limit of a simplicial, i.e. also polyhedral, spectrum  $S = \{P_n, \omega_n^m\}$ ,  $m > n$ ,  $n = 1, 2, \dots$ , (for the definitions see <sup>(2)</sup>) with projections “onto,” and moreover, if  $\dim \Phi \leq r$ , then for every  $n$  one may assume  $\dim P_n \leq r$ . The problem arose of extending Freudenthal’s results to arbitrary bicompecta. P. S. Aleksandrov and S. Mardešić (see <sup>(3)</sup>, p. 240) independently posed the question whether every  $r$ -dimensional bicompectum is the limit of a (simplicial) spectrum of  $r$ -dimensional polyhedra. *In <sup>(2)</sup> it is shown that there exists a one-dimensional in the sense of Ind (i.e. also in the sense of ind and dim) bicompectum for which there is no one-dimensional polyhedral (i.e. also simplicial) **spectrum approximating it**.* Further, it is known <sup>(5)</sup> that every bicompectum is the limit of a polyhedral spectrum with projections “into,” but it was not clear whether every bicompectum is the limit of a spectrum of polyhedra with projections “onto” \*\*\*\*. Below examples of bicompecta  $AP$  and  $AP'$  will be constructed which give a negative answer to the question posed; moreover  $\dim AP = 1$ ,  $\text{ind } AP \geq 2$ , while  $\dim AP' = \text{ind } AP' = \text{Ind } AP' = 1$ . The construction of the bicompecta  $AP$  and  $AP'$  simultaneously answers negatively the question, also posed by P. S. Aleksandrov, concerning the validity of the “sum theorem” (for a countable number of summands) for polyhedral (simplicial) spectra, namely: the bicompectum  $AP$  ( $AP'$ ), which is not the limit of any one-dimensional, nor in general of any polyhedral spectrum (with projections “onto” ), can be represented as the sum of a countable number of bicompecta  $Y_i$  ( $Y'_i$ ),  $i = 1, 2, \dots$ , which are limits of one-dimensional simplicial spectra\*\*\*\*. If spectra with projections “into” are taken, then the failure of the sum theorem for polyhedral and simplicial spectra follows from the fact that  $\dim AP = 1$ , while  $\text{ind } AP = 2$ , i.e.  $AP$  cannot be the limit of any one-dimensional polyhedral spectrum <sup>(7)</sup>.

We shall construct the bicompectum  $AP$  as the limit of a transfinite ordered spectrum of bicompecta  $X_\alpha$ . Take the set  $T$  of transfinite numbers  $\alpha \leq \omega_c$ , where  $\omega_c$  is the first ordinal number of cardinality continuum, and first divide

$T$  into continuum many pairwise disjoint sets  $T_\theta$  of cardinality continuum, and then divide each  $T_\theta$  again into continuum many pairwise disjoint sets  $T_{\theta\nu}$  of cardinality continuum. Establish a one-to-one correspondence between the indices  $\theta$  and all numbers  $c_0$  from the interval  $[0, 1]$ , and then do the same with the indices  $\theta\nu$ , for fixed  $\theta$ , and sequences of rational numbers  $c_n, n = 1, 2, \dots$ ,

---

\* The fact that every  $r$ -dimensional compactum in the sense of dim is the limit of a spectrum of  $r$ -dimensional compacta was proved by S. Mardešić in (4).

\*\* Even with projections “into.”

\*\*\* However, this bicom pactum is the limit of a simplicial (i.e. also polyhedral) spectrum of two-dimensional polyhedra with projections “onto.”

\*\*\*\* This question was posed by P. S. Aleksandrov.

\*\*\*\*\* I.e.  $\dim Y_i = \text{ind } Y_i = \text{Ind } Y_i = 1$ , whence it follows that the sum theorem for the dimensions ind and Ind is false even for summands that are limits of simplicial spectra of the corresponding dimension.

converging to  $c_0$ , with  $c_n \neq c_m$  for  $n \neq m$  and  $c_n \neq c_0$ . Thus, to each number  $\alpha$  from  $T_\theta$  there naturally corresponds a certain pair  $(c_0, \{c_n\})$ ,  $n = 1, 2, \dots$ . To distinguish the pairs corresponding to distinct  $\alpha$ , we shall mark them with the corresponding index: to the number  $\alpha$  there corresponds the pair  $(c_0^\alpha, \{c_n^\alpha\})$ ,  $n = 1, 2, \dots$ . Denote the set  $\bigcup_{n=0}^{\infty} c_n^\alpha$  by  $l_\alpha$ .

Construction of a spectrum for  $AP$ . As  $X_1$  take the “vertical” segment  $I_1 = \{(1, y), 0 \leq y \leq 1\}$ . Suppose that, for all numbers  $\alpha$  and  $\alpha' \in T$  and  $\alpha < \beta$ , the spaces  $X_\alpha$  and the projections  $\mathfrak{D}_\alpha^{\alpha'}$  have been constructed.

1) Let the number  $\beta - 1$  exist. Put

$$X_\beta = X_{\beta-1} \cup L_\beta \cup I_\beta,$$

where

$$I_\beta = \{(\beta, y), 0 \leq y \leq 1\}$$

is the “vertical” segment, and  $L_\beta$  is obtained by multiplying the “horizontal” segment

$$J_\beta = \{x_\beta, 0 \leq x_\beta \leq 1\}$$

by the set  $l_\beta$ . Thus each point of  $L_\beta$  receives two coordinates:  $x_\beta$  and  $c_n^\beta$ . The sets  $X_{\beta-1}$ ,  $L_\beta$ , and  $I_\beta$  are regarded as open in  $X_\beta$ . The projection  $\mathfrak{D}_{\beta-1}^\beta$  is defined as follows:

$$\mathfrak{D}_{\beta-1}^\beta(x_\beta, c_n^\beta) = (\beta - 1, c_n^\beta), \quad \mathfrak{D}_{\beta-1}^\beta(\beta, y) = (\beta - 1, y),$$

and on  $X_{\beta-1}$  it is the identity.

2) Suppose that  $\beta$  is a limit number. Then  $X_\beta$  is the limit of the spectrum

$$S_\beta = \{X_\alpha, \mathfrak{D}_\alpha^{\alpha'}\}, \quad \alpha < \beta,$$

and, as is not hard to see,

$$X_\beta = \bigcup_{\alpha < \beta} X_\alpha \cup I_\beta,$$

where  $X_\alpha \subset X_{\alpha'}$  when  $\alpha < \alpha'$ , and every neighborhood of the segment

$$I_\beta = \{(\beta, y), 0 \leq y \leq 1\}$$

contains all the sets  $X_{\alpha'} \setminus X_\alpha$  for some fixed  $\alpha$  and  $\alpha' > \alpha$ . We have

$$\mathfrak{D}_\alpha^\beta(\beta, y) = (\alpha, y);$$

for the remaining points,  $\mathfrak{D}_\alpha^\beta$  coincides with some (and hence with all subsequent) projection  $\mathfrak{D}_\alpha^{\alpha'}$ . The bicompectum  $AP$  is obtained as the limit of the spectrum

$$S = \{X_\alpha, \mathfrak{D}_\alpha^\beta\}, \quad \alpha < \omega_c.$$

The bicompectum  $AP'$  is a subset of  $AP$  and is obtained by deleting from  $AP$  all  $L_\beta$ , except for the subset  $1_\beta \times l_\beta$ . Since for every  $\alpha$  we have  $\dim X_\alpha = 1$ , it follows that

$$\dim AP(AP') = 1.$$

We shall write  $(x', y) < (x'', y)$  if: a)  $x' = \alpha$ ,  $x'' = \beta$ , and  $\beta > \alpha$ ; b)  $x' \in L_\alpha$ ,  $x'' \in L_\beta$ , and  $\beta > \alpha$ ; c)  $x' \in L_\alpha$ ,  $x'' = \alpha$ ; d)  $x'$  and  $x'' \in L_\beta$ , i.e.  $x' = x'_\beta$ ,  $x'' = x''_\beta$ , and  $x'_\beta < x''_\beta$ .

**Lemma 1.** Suppose we have a continuous mapping  $f$  of the bicompectum  $AP$  onto a polyhedron  $P$ . Then  $f(x, y) = f(\omega_c, y)$ , starting from some point  $(\alpha, y)$ .

**Lemma 2.** Under the conditions of the preceding lemma, for all  $y$  there exists an  $\alpha_0$  such that

$$f(x, y) = f(\omega_c, y)$$

for  $x \geq \alpha_0$ .

**Proof.** For all rational  $y$ , by Lemma 1 we find numbers  $\alpha_y$ , and, since the set of the numbers  $\alpha_y$  is countable, there exists  $\alpha_0 < \omega_c$  and  $\geq \alpha_y$  for all rational  $y$ . This  $\alpha_0$  will be the desired one, for  $f$  is continuous and the set of points  $(x, y)$  with rational second coordinates is, by construction, everywhere dense in  $AP$ , i.e., also in the set of points  $(x, y)$  with  $x \geq \alpha_0$ .

We now show that  $AP$  and  $AP'$  will not be limits of any polyhedral spectra with projections “onto.”

Suppose that the bicom pactum  $AP$  is represented as the limit of a polyhedral spectrum

$$S = \{P_\xi, \mathfrak{D}_\xi^\eta\}$$

with projections “onto.” Take a polyhedron  $P_\xi$  in which

$$\mathfrak{D}_\xi(\omega_c, 0) \neq \mathfrak{D}_\xi(\omega_c, 1).$$

Then on the segment

$$I_{\omega_c} = \{(\omega_c, y), 0 \leq y \leq 1\}$$

there will be found a point  $(\omega_c, y_0)$  such that in every neighborhood of it, relative to the segment  $I_{\omega_c}$ , there is at least one point whose image in  $P_\xi$  does not coincide with the image of the point  $(\omega_c, y_0)$ . If this is so, then there is a sequence of points  $(\omega_c, y_n)$ ,  $n = 1, 2, \dots$ , such that

$$\mathfrak{D}_\xi(\omega_c, y_n) \neq \mathfrak{D}_\xi(\omega_c, y_m) \neq \mathfrak{D}_\xi(\omega_c, y_0),$$

where the  $y_n$  are rational and converge to  $y_0$ . Consider the pair  $(c_0, \{c_n\})$  with  $c_0 = y_0$  and  $c_n = y_n$ ,  $n = 1, 2, \dots$ . By Lemma 2, for  $\mathfrak{D}_\xi$  we find  $\alpha_0$ . There exists such a  $\beta_0 \geq \alpha_0$  that

$$(c_0^{\beta_0}, \{c_n^{\beta_0}\}) = (c_0, \{c_n\}),$$

for the indices  $\beta$  to which the pair  $(c_0, \{c_n\})$  corresponds form a continuum, i.e. they

occur arbitrarily far away. Now take in the spectrum  $S$  a polyhedron  $P_\eta$ ,  $\eta > \xi$ , in which

$$\mathfrak{F}_\eta(L_{\beta_0}) \cap \mathfrak{F}_\eta(AP \setminus L_{\beta_0}) = \Lambda,$$

i.e. the image  $P_\eta^*$  of the set  $L_{\beta_0}$  is open and closed in  $P_\eta$  (such a polyhedron  $P_\eta$  can always be found, since  $L_{\beta_0}$  is open and closed in  $AP$ ). The polyhedron  $P_\eta^*$  must contain a countable number of pairwise disjoint open-and-closed sets

$$\mathfrak{F}_\eta(J_{\beta_0} \times c_n^{\beta_0}), \quad n = 1, 2, \dots,$$

since

$$\mathfrak{F}_\xi(J_{\beta_0} + c_n^{\beta_0}) = \mathfrak{F}_\xi(\omega_c, y_n = c_n^{\beta_0}) \neq \mathfrak{F}_\xi(\omega_c, y_m = c_m^{\beta_0}) = \mathfrak{F}_\xi(J_{\beta_0} \times c_m^{\beta_0})$$

for  $m \neq n$  and  $\eta > \xi$ . But, being a polyhedron,  $P_\eta^*$  cannot contain a countable number of open-and-closed sets. We have arrived at a contradiction. In a completely analogous way the proof of the absence of a polyhedral spectrum with projections “onto” is also carried out for  $AP'$ . In fact, it is easy to see that we have proved even more, namely: *the bicom pacts  $AP$  and  $AP'$  are not limits of any spectra of locally connected compacta with projections “onto.”*

We now represent the bicomact  $AP$  ( $AP'$ ) as a countable sum of bicomacts  $Y_i$  possessing one-dimensional simplicial spectra. Put

$$Y_i = \bigcup_{\alpha < \omega_c} I_\alpha \cup \bigcap_{\alpha < \omega_c} (J_\alpha \times c_i^\alpha), \quad i = 0, 1, 2, \dots,$$

where the topology in  $Y_i$  is induced by the bicomact  $AP$ . We shall construct a one-dimensional simplicial spectrum of polyhedra, for example, for  $Y_0$ . The indices of the required spectrum will be all possible finite sets  $a = (\alpha_1, \dots, \alpha_s)$  of numbers  $\alpha < \omega_c$ , ordered by inclusion. We construct  $P_a$ , for example, for  $a = (\alpha_1, \alpha_2)$ . This will be the sum of intervals in the coordinate plane  $xOy$ :

$$I_{\alpha_1}^a = \{(x, y), x = 0, 0 \leq y \leq 1\},$$

$$J_{\alpha_1+1}^a = \{(x, y), 1 \leq x \leq 2, y = c_0^{\alpha_1+1}\},$$

$$I_{\alpha_2}^a = \{(x, y), x = 3, 0 \leq y \leq 1\},$$

$$J_{\alpha_2+1}^a = \{(x, y), 4 \leq x \leq 5, y = c_0^{\alpha_2+1}\}$$

and

$$I^a = \{(x, y), x = 6, 0 \leq y \leq 1\}.$$

Put

$$\mathfrak{F}_a(x, y) = \{(0, y) \text{ for } x \leq \alpha_1; (x_{\alpha_1+1} + 1, c_0^{\alpha_1+1}) \text{ for } (x, y) \in J_{\alpha_1+1} \times c_0^{\alpha_1+1};$$

$$(3, y) \text{ for } \alpha_1 + 1 \leq x \leq \alpha_2; (x_{\alpha_2+1} + 4, c_0^{\alpha_2+1}) \text{ for } (x, y) \in J_{\alpha_2+1} \times c_0^{\alpha_2+1},$$

and, finally,

$$(6, y) \text{ for } x \geq \alpha_2 + 1\}.$$

The spectrum thus constructed will be simplicial and one-dimensional. In the case of the bicomact  $AP'$  we proceed analogously.

It remains to show further that

$$\dim AP' = \text{ind } AP' = \text{Ind } AP' = 1$$

and that

$$\text{ind } AP' \geq 2.$$

We first prove the second assertion, i.e. that  $\text{ind } AP \geq 2$ . The proof is similar to those carried out in a like situation earlier (see, for example, (6)). Take the point  $M_0 = (\omega_c, 0)$  and consider its neighborhood  $OM_0$ , assuming that

$$[OM_0] \cap (E_1 = \{(x, y), y = 1\}) = \Lambda.$$

Let the point  $(\omega_c, y_0)$  be the upper boundary of the points of  $OM_0$  on the interval  $I_{\omega_c}$ . For each point  $(\omega_c, y')$  of the set

$$O_{\omega_c} = OM_0 \cap I_{\omega_c}$$

one can find a basic neighborhood

$$O_{y'} = \{(x, y), x \geq \alpha_{y'}, 0 \leq y'_1 \leq y \leq y'_2 < y_0\},$$

contained in  $OM_0$ . One can cover the whole set  $O_{\omega_c}$  by a countable number of such neighborhoods  $O_{y'_k}$ , and take  $\alpha_0 < \omega_c$  and  $\geq$  all  $\alpha_{y'_k}$ . It is clear that for  $x \geq \alpha_0$  and  $y < y_0$  all points  $(x, y)$  belong to  $OM_0$ , i.e. for  $y = y_0$ , for arbitrarily large  $\alpha$ , there exist intervals

$$J_\alpha \times (c_0^\alpha = y_0)$$

from  $L_\alpha$  belonging to  $[OM_c]$ . Such  $\alpha$  will be, for example, those in the corresponding pairs  $(c_0^\alpha = y_0, \{c_n^\alpha\})$  for which  $c_n^\alpha$  converge to  $c_0^\alpha = y_0$  both from above and from below. It is precisely such  $\alpha$  that we shall consider further. If at least one of the intervals

$$J_\alpha \times (c_0^\alpha = y_0)$$

belongs to

$$\text{Fr } \rho OM = [OM_0] \setminus OM_0,$$

then  $\text{ind Fr } \rho OM_0 \geq 1$ . Suppose that no such interval belongs entirely to  $\text{Fr } \rho OM_0$ . Then for all, i.e. for arbitrarily large,  $\alpha$ , to which pairs

$$(c_0^\alpha = y_0, \{c_n^\alpha\})$$

correspond (where  $c_n^\alpha$  converge to  $c_0^\alpha$  both from above and from below), on the intervals  $J_\alpha \times y_0$  there is at least one point  $M_\alpha = (x_\alpha, y_0)$  belonging to  $OM_0$ , i.e.  $OM_0$  contains also some neighborhood  $OM_{x_\alpha}$ ,

and hence also some sequence of points  $(x_\alpha, y_k)$ ,  $y_k = c_{n_k}^\alpha > y_0$ . We now show that all points of some segment  $\omega_c \times [y_0, y_1]$ ,  $y_1 > y_0$ , belong to the closure of  $OM_0$ . If there were no such segment, then there would exist a sequence of rational points  $\{y_{2l}\}$ ,  $l = 1, 2, \dots$ ,  $y_{2l} > y_0$  and  $\neq y_{2m}$  for  $m \neq l$ , converging to  $y_0$  and not belonging to  $[OM_0]$ . Take such a fixed pair  $(c_0 = y_0, \{c_n\})^0$  that for  $n = 2l$  we have  $c_n = y_{2l}$ , while for  $n = 2l - 1$  all  $y_n < y_0$ . The indices  $\beta$  for which  $(c_0^\beta, \{c_n^\beta\}) = (c_0, \{c_n\})^0$  form a continuum; hence, as was shown above,  $OM_0$  contains the points  $(x_\beta, y_{2l})$  for  $l \geq N_\beta$  for a continuum of numbers  $\beta$ , i.e., for a continuum of numbers  $\beta$  the numbers  $N_\beta$  coincide and are equal to  $N$ ; that is, for arbitrarily large  $\beta$ ,  $OM_0$  contains the points  $(x_\beta, y_{2l})$ ,  $l \geq N$ . It is now clear that the points  $(\omega_c, y_{2l})$  for  $l \geq N$  are contained in  $[OM_0]$ . We obtain a contradiction to the fact that  $\Gamma pOM_0$  contains no segment  $\omega_c \times [y_0, y_1]$ . Thus, in every case  $\text{ind } \Gamma pOM_0 \geq 1$ , i.e.  $\text{ind } AP$  and  $\text{Ind } AP \geq 2$ . The fact that  $\text{ind } AP' = 1$  is sufficiently obvious, and then also  $\text{Ind } AP' = 1$ . Thus, bicompecta that are not limits of polyhedral spectra (and even spectra of locally connected compacta) with “onto” projections may be both bicompecta with coinciding dimensions  $\text{ind}$ ,  $\text{Ind}$ , and  $\text{dim}$ , and with noncoinciding ones.

The author expresses sincere gratitude to P. S. Aleksandrov for proposing the problems solved here.
