## ON INCLINATIONS OF SUBSPACES AND CONDITIONAL BASES IN BANACH SPACE

*(Presented by Academician A. N. Kolmogorov, 23 II 1962)*

Let  $P$  and  $Q$  be linear manifolds in a Banach space  $E$ . Define the inclination of  $P$  to  $Q$  as the quantity

$$(\widehat{P; Q}) = \inf_{\substack{x \in P, y \in Q \\ \|x\|=1}} \|x + y\|.$$

Denote by  $L_{\{f_1, \dots, f_n\}}$  the linear span of the elements  $f_1, \dots, f_n$ ;  $f_i \in E$  ( $i = 1, 2, \dots, n$ ), and call the index of the collection  $\{f_i\}_{i=1}^n$  the quantity

$$\gamma_{\{f_1, \dots, f_n\}} = \min_{1 \leq p < n} (L_{\{f_1, \dots, f_p\}}; \widehat{L_{\{f_{p+1}, \dots, f_n\}}}).$$

Analogously, the index of a sequence  $\{f_i\}_{i=1}^{\infty}$ ,  $f_i \in E$ , is defined as

$$\gamma_{\{f_1, \dots, f_n, \dots\}} = \inf_n \gamma_{\{f_1, \dots, f_n\}}.$$

As was shown by M. M. Grinblum <sup>(1)</sup>, in order that a sequence  $\{f_i\}_{i=1}^{\infty}$  complete in  $E$  be a basis\* in  $E$ , it is necessary and sufficient that the condition  $\gamma_{\{f_1, f_2, \dots\}} > 0$  be satisfied.

From the results of K. I. Babenko <sup>(2)</sup> and V. G. Vinokurov <sup>(3)</sup> it follows that in Hilbert spaces and in some classes of Banach spaces there exist subspaces with conditional bases. Here a generalization of this assertion to arbitrary infinite-dimensional Banach spaces will be obtained. Theorems 1-4 will serve as the apparatus for obtaining the results.

**Theorem 1.** *For given  $\varepsilon > 0$  and a finite-dimensional subspace  $P \subset E$  of an infinite-dimensional Banach space  $E$ , there exists an infinite-dimensional subspace  $Q \subset E$  such that  $(\widehat{P; Q}) > 1 - \varepsilon$ .*

**Proof.** On the basis of the Banach-Mazur theorem one may regard  $E$  as a subspace of  $C_{[0;1]}$ . The unit sphere  $S_P$  of the finite-dimensional subspace  $P$  is compact in  $C_{[0;1]}$  and, consequently, constitutes a family of functions equicontinuous on  $[0; 1]$ . Therefore, for the given  $\varepsilon > 0$  there is a natural number  $n$  such that if  $|x_1 - x_2| < 1/n$ , then  $|f(x_1) - f(x_2)| < \varepsilon$  for every  $f(x) \in S_P$ .

Consider the set  $Q$  of functions from  $E$  that vanish at the points  $x_k = k/n$ ,  $k = 0, 1, \dots, n$ . It is not difficult to verify that  $Q$  is an infinite-dimensional subspace of the space  $E$ .

---

\* A sequence  $\{f_i\}_1^\infty$  is called a basis in  $E$  if every element  $f \in E$  can be represented in a unique way in the form

$$f = \sum_{i=1}^{\infty} \alpha_i f_i.$$

A sequence  $\{f_i\}_1^\infty$  that remains a basis in  $E$  under any permutation of its elements is called an unconditional basis in  $E$ . A basis that is not unconditional is called a conditional basis.

For the given  $f(x) \in S_P$  and  $g(x) \in Q$ , let  $\tilde{x}$  be one of the points at which  $|f(x)|$  assumes its maximum; then for some natural  $i_0 \leq n$ ,

$$\frac{i_0 - 1}{n} \leq \tilde{x} \leq \frac{i_0}{n}.$$

We have:

$$\begin{aligned} \max_{x \in [0;1]} |f(x) - g(x)| &\geq \max_{i=0,1,\dots,n} \left| f\left(\frac{i}{n}\right) - g\left(\frac{i}{n}\right) \right| = \\ &= \max_{i=0,1,\dots,n} \left| f\left(\frac{i}{n}\right) \right| \geq \left| f\left(\frac{i_0}{n}\right) \right| \geq |f(\tilde{x})| - \varepsilon = 1 - \varepsilon. \end{aligned}$$

This inequality means that  $(\widehat{P;Q}) \geq 1 - \varepsilon$ . The theorem is proved.

**Lemma.** Let, for linear manifolds  $P_1, P_2 = Q + R$ , and  $P_3$  in a Banach space, the following conditions be satisfied:

1.  $(\widehat{Q;R}) \geq \alpha > 0$ .
2.  $(P_1 + \widehat{P_2;P_3}) \geq \beta; (P_1; \widehat{P_2 + P_3}) \geq \beta; \beta > 0$ .

Then

$$(P_1 + Q; R + P_3) \geq \frac{\alpha\beta}{2 + \alpha}.$$

From the lemma there follows directly the following theorem on the possibility of “synthesizing” a basis in a space from bases in its subspaces.

**Theorem 2.** Let  $\{f_i^{(1)}, f_i^{(2)}, \dots, f_i^{(k_i)}\}$ ,  $i = 1, 2, \dots$ , be bases in  $k_i$ -dimensional subspaces  $P_i \subset E$ , and let

$$\gamma_{\{f_i^{(1)}, \dots, f_i^{(k_i)}\}} \geq \alpha > 0, \quad i = 1, 2, \dots,$$

and, for any natural  $m, n, m < n$ ,

$$(P_1 + \dots + \widehat{P_m}; P_{m+1} + \dots + P_n) \geq \beta > 0.$$

Then the sequence

$$f_1^{(1)}, \dots, f_1^{(k_1)}, f_2^{(1)}, \dots, f_2^{(k_2)}, \dots, f_i^{(1)}, \dots, f_i^{(k_i)}, \dots$$

is a basis in its closed linear span, and

$$\gamma_{\{f_1^{(1)}, \dots, f_1^{(k_1)}, \dots, f_2^{(1)}, \dots\}} \geq \frac{\alpha\beta}{2 + \alpha}.$$

The result obtained below makes essential use of an important theorem on  $\varepsilon$ -isometry of Banach spaces due to A. Dvoretzky (4).

**Definition.** Banach spaces  $E_1$  and  $E_2$  are called  $\varepsilon$ -isometric if there exists an isomorphic mapping  $T$  from  $E_1$  onto  $E_2$  such that, for any  $f \in E_1$ ,

$$(1 - \varepsilon)\|f\| \leq \|Tf\| \leq (1 + \varepsilon)\|f\|.$$

**Theorem 3 (A. Dvoretzky).** For every  $\varepsilon > 0$  and natural  $n$  there exists a natural  $N_0(n; \varepsilon)$  such that every  $N$ -dimensional Banach space, for  $N > N_0$ , contains an  $n$ -dimensional subspace  $\varepsilon$ -isometric to  $n$ -dimensional Euclidean space.

From the cited results of K. I. Babenko, M. M. Grinblyum, and A. Dvoretzky it follows:

**Theorem 4.** In an infinite-dimensional Banach space  $E$ , for every  $\varepsilon > 0$  there can be found a collection of elements  $f_1, \dots, f_n, n = n(\varepsilon)$ , such that  $\gamma_{\{f_1, \dots, f_n\}} > \alpha > 0$ , where  $\alpha$  is an absolute constant, and under a suitable permutation of the elements the index of this collection becomes less than  $\varepsilon$ .

**Theorem 5.** In every infinite-dimensional Banach space there exists a sequence  $\{f_i\}_{i=1}^{\infty}$  which is a conditional basis in the closure of its linear span.

**Proof.** Consider a sequence of numbers  $\{\varepsilon_i\}_{i=1}^{\infty}$  satisfying the conditions:  $0 < \varepsilon_i < 1$  and

$$\prod_{i=1}^{\infty} (1 - \varepsilon_i) = \beta > 0.$$

By Theorem 4, in the given Banach space  $E$  there exists a collection of elements  $\{f_1^{(1)}, f_1^{(2)}, \dots, f_1^{(k_1)}\}$  such that

$$\gamma_{\{f_1^{(1)}, \dots, f_1^{(k_1)}\}} > \alpha > 0,$$

but, under a suitable permutation of its elements, we shall have

$$\gamma_{\{\tilde{f}_1^{(1)}, \dots, \tilde{f}_1^{(k_1)}\}} < \varepsilon_1.$$

Denote by  $P_1$  the subspace spanned by  $f_1^{(1)}, \dots, f_1^{(k_1)}$ , and consider an infinite-dimensional subspace  $Q_1 \subset E$  such that

$$(P_1, Q_1) > 1 - \varepsilon_1$$

(the existence of such a subspace is ensured by Theorem 1).

In the subspace  $Q_1$  there exists a collection of elements  $\{f_2^{(1)}, \dots, f_2^{(k_2)}\}$  such that

$$\gamma_{\{f_2^{(1)}, \dots, f_2^{(k_2)}\}} > \alpha,$$

but, under a suitable permutation of the elements, we shall have

$$\gamma_{\{\tilde{f}_2^{(1)}, \dots, \tilde{f}_2^{(k_2)}\}} < \varepsilon_2.$$

Denote by  $P_2$  the subspace spanned by  $f_2^{(1)}, \dots, f_2^{(k_2)}$ , and consider an infinite-dimensional subspace  $Q_2 \subset E$  such that

$$(P_1 + P_2, Q_2) > 1 - \varepsilon_2.$$

Continuing this process indefinitely, we obtain a collection of a sequence of finite-dimensional subspaces  $\{P_i\}_{i=1}^{\infty}$  with bases  $\{f_i^{(1)}, \dots, f_i^{(k_i)}\}$ , for which we have

$$\gamma_{\{f_i^{(1)}, \dots, f_i^{(k_i)}\}} > \alpha$$

and

$$\gamma_{\{\tilde{f}_i^{(1)}, \dots, \tilde{f}_i^{(k_i)}\}} < \varepsilon_i$$

(the collection  $\{\tilde{f}_i^{(1)}, \dots, \tilde{f}_i^{(k_i)}\}$  is obtained from the collection  $\{f_i^{(1)}, \dots, f_i^{(k_i)}\}$  by some permutation of the elements), and, moreover,

$$(P_1 + P_2 + \dots + P_i, Q_i) > 1 - \varepsilon_i, \quad i = 1, 2, \dots$$

Since  $P_{i+1} \subset Q_i$ , it follows that

$$(P_1 + P_2 + \dots + P_i, P_{i+1}) \geq (P_1 + P_2 + \dots + P_i, Q_i) > 1 - \varepsilon_i.$$

Let us show that the sequence

$$\{f_1^{(1)}, \dots, f_1^{(k_1)}, f_2^{(1)}, \dots, f_2^{(k_2)}, \dots\}$$

forms a basis in the subspace  $P \subset E$  spanned by it.

Let

$$f \in P_1 + \dots + P_m, \quad g \in P_{m+1} + \dots + P_{m+n}, \quad g = g_1 + g_2 + \dots + g_n,$$

where  $g_k \in P_{m+k}$ ,  $k = 1, 2, \dots, n$ . We have:

$$\begin{aligned} \|f + g\| &= \|(f + g_1 + \dots + g_{n-1}) + g_n\| \\ &\geq (1 - \varepsilon_{m+n-1})\|f + g_1 + \dots + g_{n-1}\| \\ &\geq (1 - \varepsilon_{m+n-1})(1 - \varepsilon_{m+n-2})\|f + g_1 + \dots + g_{n-2}\| \geq \dots \\ &\geq (1 - \varepsilon_{m+n-1})(1 - \varepsilon_{m+n-2}) \dots (1 - \varepsilon_m)\|f\| \geq \beta\|f\|. \end{aligned}$$

This inequality means that

$$(P_1 + \dots + P_m, P_{m+1} + \dots + P_{m+n}) \geq \beta,$$

and, by Theorem 2, the sequence

$$f_1^{(1)}, \dots, f_1^{(k_1)}, f_2^{(1)}, \dots, f_2^{(k_2)}, \dots$$

is a basis in  $P$ . This basis is conditional, since by a permutation of its elements one can obtain the sequence

$$\tilde{f}_1^{(1)}, \dots, \tilde{f}_1^{(k_1)}, \tilde{f}_2^{(1)}, \dots, \tilde{f}_2^{(k_2)}, \dots,$$

for which, in view of the fact that  $\lim_{i \rightarrow \infty} \varepsilon_i = 0$ , we have:

$$\gamma_{\{\tilde{f}_1^{(1)}, \dots, \tilde{f}_1^{(k_1)}, \tilde{f}_2^{(1)}, \dots, \tilde{f}_2^{(k_2)}, \dots\}} = 0.$$

The theorem is proved.
