## CYBERNETICS AND CONTROL THEORY

**E. I. NECHIPORUK**

### ON SELF-CORRECTING GATE CIRCUITS

*(Presented by Academician P. S. Novikov on 20 I 1964)*

In this note self-correcting <sup>(1)</sup> gate circuits are considered. In gate circuits two kinds of malfunctions are possible: shorting, or breakdown, and disconnection of gates. Below estimates are given for the complexity of gate circuits of depth 2 <sup>(2)</sup> that correct disconnections of gates. It is shown that the complexity of circuits correcting  $m$ -fold disconnections increases, in comparison with the complexity of ordinary circuits, by no less than  $C(m+1)$  times, where  $C$  is a certain constant, and in the case of not too "dense" matrices—asymptotically by  $m+1$  times. Thus the case considered here differs substantially from the case of correction of a single shorting in contact circuits <sup>(1)</sup>, where no (asymptotic) increase of complexity is required in comparison with ordinary circuits.

1°. Denote by  $\chi(\mathfrak{A})$  the matrix realized by the gate circuit  $\mathfrak{A}$ . Denote by  $\mathfrak{M}_m(\mathfrak{A})$  the set of all circuits obtained from the circuit  $\mathfrak{A}$  by disconnecting no more than  $m$  arbitrary gates. We shall say that the circuit  $\mathfrak{A}$  corrects  $m$ -fold disconnections if for every circuit  $\mathfrak{C}$  from  $\mathfrak{M}_m(\mathfrak{A})$  the equality  $\chi(\mathfrak{C}) = \chi(\mathfrak{A})$  holds.

Denote by  $B(\mathfrak{A})$  the number of gates in the circuit  $\mathfrak{A}$ . For an arbitrary matrix  $A^*$  introduce the function  $B_{r,m}(A) = \min B(\mathfrak{A})$ , where the minimum is taken over all circuits  $\mathfrak{A}$  of depth no greater than  $r$ , realizing the matrix  $A$  and correcting  $m$ -fold disconnections. For an arbitrary class of matrices  $\mathfrak{N}$  introduce the function  $B_{r,m}(\mathfrak{N}) = \max B_{r,m}(A)$ , where the maximum is taken over all matrices  $A$  from  $\mathfrak{N}$ . The functions  $B_{r,0}$  refer to ordinary circuits without self-correction. We shall call the number

$$\beta_{r,m}(\mathfrak{N}) = \frac{B_{r,m}(\mathfrak{N})}{B_{r,0}(\mathfrak{N})}$$

the duplication coefficient.

Obviously, for any  $r, \mathfrak{N}$ ,  $\beta_{r,m}(\mathfrak{N}) \leq m+1$ .

**Lemma 1.** *In order that a circuit correct  $m$ -fold disconnections, it is necessary and sufficient that in it, between any pair of poles with nonzero conductivity, there exist no fewer than  $m+1$  distinct chains having no pairwise common gates.*

**Proof** follows from the "transport" theorem of Ford-Fulkerson <sup>(3)</sup>.

Fig. 1

Figure 1: Fig. 1

Denote by  $\|A\|$  the number of ones in the matrix  $A$ . We shall call a matrix having  $s$  rows and  $t$  columns an  $(s, t)$ -matrix; an  $(s, t)$ -matrix will be called nondegenerate if  $s > 0, t > 0$ ; a nondegenerate matrix consisting only of ones will be called complete. We shall call a circuit  $\mathfrak{A}$  nondegenerate if  $\chi(\mathfrak{A})$  is a nondegenerate nonzero matrix. Let  $a$  be a nondegenerate  $(s, t)$ -matrix,  $A$  a nondegenerate nonzero matrix. Introduce the densities of matrices:

$$d(a) = d(s, t) = \begin{cases} \frac{st}{s+t}, & \text{for } s > 1, t > 1, \\ 1, & \text{for } s = 1 \text{ or } t = 1; \end{cases}$$

$$\delta(A) = \max d(a),$$

where the maximum is taken over all complete submatrices  $a$  of the matrix  $A$ ;

$$\delta(\mathfrak{A}) = \min_{A \in \mathfrak{A}} \delta(A).$$

**Theorem 1.** *If  $A$  is a nondegenerate nonzero matrix, then*

$$(m+1) \frac{\|A\|}{\delta(A)} \leq B_{2,m}(A).$$

---

\* All matrices are considered Boolean.

**Proof.** Let  $B_{2,m}(A)$  be attained on a nondegenerate  $(p, q)$ -circuit  $\mathfrak{A}$  of depth at most 2. Obviously,  $\mathfrak{A}$  has no “superfluous” gates. We decompose  $\mathfrak{A}$  into subcircuits  $\mathfrak{A}_k$ , pairwise intersecting only at poles, so that  $\mathfrak{A}_0$  is a circuit of depth at most 1, while  $\mathfrak{A}_k$  for  $k \geq 1$  are circuits of depth 2 containing only one internal node (Fig. 1). We assume that every subcircuit  $\mathfrak{A}_k$  contains all the poles of the circuit  $\mathfrak{A}$ . Denote by  $\varphi_k^{i,j}$  the largest number of chains containing no pairwise common gates (a flow) between the poles with numbers  $i, j$  in the subcircuit  $\mathfrak{A}_k$ . Every chain of the circuit  $\mathfrak{A}$  belongs to one and only one subcircuit  $\mathfrak{A}_k$ ; therefore (Lemma 1)

**Fig. 1**

$$(m+1)\|A\| \leq \sum_k \sum_{i,j} \varphi_k^{i,j}. \quad (1)$$

We shall show that, for nondegenerate subcircuits  $\mathfrak{A}_k$ ,

$$\sum_{i,j} \varphi_k^{i,j} \leq \delta(\chi(\mathfrak{A}_k)) B(\mathfrak{A}_k). \quad (2)$$

For  $k = 0$ , (2) is obvious. Let  $k \geq 1$ . Denote by  $a_i$  and  $b_j$  (we omit the index  $k$ ) the number of gates connecting the internal node of the subcircuit  $\mathfrak{A}_k$  with the  $i$ -th input and the  $j$ -th output, respectively. Obviously,  $\varphi^{i,j} = \min(a_i, b_j)$ . Let  $s$  be the number of inputs and  $t$  the number of outputs connected with the internal node of the subcircuit  $\mathfrak{A}_k$ . Renumber the nonzero  $a_i, b_j$  by the numbers  $u = 1, \dots, s, v = 1, \dots, t$ . Since

$$\frac{st}{s+t} \leq \delta(\chi(\mathfrak{A}_k)), \quad B(\mathfrak{A}_k) = \sum_{u=1}^s a_u + \sum_{v=1}^t b_v,$$

(2) follows from the easily verified inequality

$$\sum_{u=1}^s \sum_{v=1}^t \min(a_u, b_v) \leq \frac{st}{s+t} \left( \sum_{u=1}^s a_u + \sum_{v=1}^t b_v \right).$$

The assertion of the theorem follows from (1), (2), since

$$\max \delta(\chi(\mathfrak{A}_k)) \leq \delta(A), \quad B_{2,m}(A) = B(\mathfrak{A}) = \sum_k B(\mathfrak{A}_k).$$

2°. Denote by  $\mathfrak{B}(p, q, \alpha)$  the class of all  $(p, q)$ -matrices containing  $\alpha pq$  ones (the conditions  $0 \leq \alpha \leq 1$  and that  $\alpha pq$  is an integer are assumed to hold everywhere, without further mention). Put  $\alpha^* = \min(\alpha, 1 - \alpha)$  and

$$H(z) = z \lg_2 \frac{1}{z} + (1-z) \lg_2 \frac{1}{1-z}. \quad (3)$$

**Theorem 2.** Suppose the following conditions are satisfied:

- a)  $q_n \leq p_n$ ;
- b)  $q_n \rightarrow \infty$ ;
- c)

$$\frac{\alpha_n \lg_2 \frac{1}{\alpha_n} q_n}{\lg_2 p_n} \rightarrow x;$$

- d)

$$\frac{\lg_2 p_n}{\lg_2 \frac{1}{\alpha_n^*}} \rightarrow \infty *.$$

\* Conditions c), d) mean that the matrices from the classes  $\mathfrak{B}(p_n, q_n, \alpha_n)$  are not too “narrow” and not too “sparse” or “dense.”

Then

$$\delta(\mathfrak{B}(p_n, q_n, \alpha_n)) \sim \frac{\lg_2 p_n}{\lg_2 \frac{1}{\alpha_n}}.$$

**Proof.** The lower bound follows from the existence in every matrix from  $\mathfrak{B}(p_n, q_n, \alpha_n)$  of a complete  $(s_n, t_n)$ -submatrix such that

$$t_n \sim \frac{\lg_2 p_n}{\lg_2 \frac{1}{\alpha_n}}, \quad \frac{s_n}{t_n} \rightarrow \infty \quad (4)$$

(the numbers  $s_n, t_n$  are the same for all matrices from  $\mathfrak{B}(p_n, q_n, \alpha_n)$ ). Indeed, from (4)

$$\delta(\mathfrak{B}(p_n, q_n, \alpha_n)) \geq \frac{s_n t_n}{s_n + t_n} \sim \frac{\lg_2 p_n}{\lg_2 \frac{1}{\alpha_n}}.$$

As in (4), it is easy to show that for every  $t_n$ , not greater than  $[\alpha_n q_n]$ , in every matrix from  $\mathfrak{B}(p_n, q_n, \alpha_n)$  there exists a complete  $(s_n, t_n)$ -submatrix, where

$$s_n = \left[ p_n \frac{C_{[\alpha_n q_n]}^{t_n}}{C_{q_n}^{t_n}} \right] * . \quad (5)$$

We shall show that for a certain choice of the number  $t_n$  the pair  $(s_n, t_n)$  satisfies the conditions (4). Put

$$t_n \rightarrow \infty, \quad \frac{t_n}{\alpha_n q_n} \rightarrow 0. \quad (6)$$

In view of c), d) these conditions are compatible and follow from (4). From (5)

$$\lg_2 s_n \geq \lg_2 p_n + H\left(\frac{t_n}{\alpha_n q_n}\right) \alpha_n q_n - H\left(\frac{t_n}{q_n}\right) q_n + o(1) = \lg_2 p_n - t_n \lg_2 \frac{1}{\alpha_n} -$$

$$-(\alpha_n q_n - t_n) \lg_2 \left(1 - \frac{t_n}{\alpha_n q_n}\right) + (q_n - t_n) \lg_2 \left(1 - \frac{t_n}{q_n}\right) + o(1) =$$

$$= \lg_2 p_n - t_n \lg_2 \frac{1}{\alpha_n} - \frac{1 - \alpha_n}{\alpha_n} \frac{t_n^2}{q_n} (1 + o(1)) \lg_2 e + o(1) \quad **.$$

Introduce a parameter  $\varepsilon_n$  and put

$$t_n = \left[ \begin{array}{c} (1 - \varepsilon_n) \frac{\lg_2 p_n}{1} \\ \lg_2 \frac{1}{\alpha_n} \end{array} \right].$$

Then

$$\lg_2 s_n \geq \varepsilon_n \lg_2 p_n - \frac{1 - \alpha_n}{\alpha_n} \frac{t_n^2}{q_n} (1 + o(1)) \lg_2 e + o(1).$$

Put

$$\lambda_n = \frac{\lg_2 p_n}{\lg_2 \frac{1}{\alpha_n}}, \quad \omega_n = \frac{\lg_2 \frac{1}{\alpha_n} q_n}{\lg_2 p_n}, \quad \varphi_n = \frac{\lg_2 p_n}{\lg_2 \lambda_n}.$$

In view of d),  $\varphi_n \rightarrow \infty$ . The conditions (4) follow from the conditions  $\varepsilon_n \rightarrow 0$ ,  $\varepsilon_n \omega_n \rightarrow \infty$  \*\*\*,  $\varepsilon_n \varphi_n \rightarrow \infty$ . Put

$$\varepsilon_n = (\min(\omega_n, \varphi_n))^{-1/2}.$$

Then all the conditions are fulfilled.

\*  $[a]$  ( $\lceil a \rceil$ ) denotes the integer nearest to  $a$  from below (from above).

\*\* The following facts are used: Stirling's formula, (6),  $H(z)$  increases monotonically in a neighborhood of zero,  $H(0) = 0$ , (3),  $\lg_2(1-z) = -z(1+o(1)) \lg_2 e$  as  $z \rightarrow 0$ .

$$*** \quad \varepsilon_n \lg_2 p_n \frac{\alpha_n q_n}{(1 - \alpha_n) t_n^2} \asymp \varepsilon_n \omega_n \frac{\lg_2 \frac{1}{\alpha_n}}{1 - \alpha_n} \rightarrow \infty, \quad \text{since } \frac{\lg_2 \frac{1}{\alpha_n}}{1 - \alpha_n} \geq 1.$$

**Upper estimate.** Denote by  $S(p, q, \alpha, s, t)$  the number of matrices from  $\mathfrak{B}(p, q, \alpha)$  having at least one complete  $(s, t)$ -submatrix. We have

$$S(p, q, \alpha, s, t) \leq C_p^s C_q^t C_{pq-st}^{\alpha pq-st}.$$

Denote by  $\varkappa_n$  the cardinality of the class  $\mathfrak{B}(p_n, q_n, \alpha_n)$ . Put  $\nu_n = \frac{\lg_2 q_n}{\lg_2 p_n}$ . Under conditions a), b) and  $s_{nt}n = o(\alpha_n p_n q_n)$ , we have

$$\lg_2 \frac{S(p_n, q_n, \alpha_n, s_n, t_n)}{\varkappa_n} \leq (s_n + \nu_n t_n) \lg_2 p_n - s_{nt}n \lg_2 \frac{1}{\alpha_n}. \quad (7)$$

Suppose the upper estimate is false. Then there exist a number  $\omega$ , greater than one, and a subsequence of  $\{n\}$  (for it we retain the notation  $\{n\}$ ) such that for every matrix  $A_n$  from  $\mathfrak{B}(p_n, q_n, \alpha_n)$ ,  $\omega\lambda_n \leq \delta(A_n)$ , i.e., every matrix  $A_n$  contains a complete  $(u_n, v_n)$ -submatrix  $a_n$  ( $u_n, v_n$  depend on  $A_n$ ) for which  $\omega\lambda_n \leq d(a_n)$ . Every matrix  $a_n$  contains a complete  $(s_n, t_n)$ -submatrix  $b_n$  ( $s_n, t_n$  depend on  $a_n$ ) such that  $s_{nt}n = o(\alpha_n p_n q_n)$  and  $\omega\lambda_n \leq d(b_n)$ . Indeed, without loss of generality assume that  $v_n \leq u_n$ . If  $v_n \leq 2\omega\lambda_n$ , put  $(s_n, t_n) = (u_n, v_n)$ ; if  $2\omega\lambda_n < v_n$ , put  $s_n = t_n = \lfloor 2\omega\lambda_n \rfloor$ . Condition  $s_{nt}n = o(\alpha_n p_n q_n)$  follows from c). But when  $\omega\lambda_n \leq d(b_n)$ , the right-hand side of (7) tends to  $-\infty$ , i.e., as  $n$  grows, almost all matrices from  $\mathfrak{B}(p_n, q_n, \alpha_n)$  contain no complete  $(s_n, t_n)$ -submatrices. The contradiction obtained completes the proof of the theorem.

**Corollary.** Under the conditions of Theorem 2,

$$\frac{\alpha_n \lg_2 \frac{1}{\alpha_n}}{H(\alpha_n)} (m+1) \leq \beta_{2,m}(\mathfrak{B}(p_n, q_n, \alpha_n)) \leq m+1.$$

Indeed, from (5),

$$B_{2,0}(\mathfrak{B}(p_n, q_n, \alpha_n)) \sim H(\alpha_n) \frac{p_n q_n^n}{\lg_2 p_n}.$$

**Theorem 3.** Under the conditions of Theorem 2 and  $\alpha_n \rightarrow 0$ ,

$$\beta_{2,m}(\mathfrak{B}(p_n, q_n, \alpha_n)) \sim m+1.$$

**Theorem 4.** If  $\min(p_n, q_n) \rightarrow \infty$ , then for the class of all  $(p_n, q_n)$ -matrices

$$\frac{m+1}{e \ln 2} \leq \beta_{2,m} \leq m+1.$$

**Proof.** From the corollary,

$$(m + 1) \max \left( \alpha, \lg_2 \frac{1}{\alpha} \right) \leq \beta_{2,m}.$$

The maximum is attained at  $\alpha = \frac{1}{e}$ .
