## **ON REPRESENTING SMALL CATEGORIES**

*(Presented by Academician P. S. Novikov on 1 VII 1964)*

**1. Notation and definitions.** The letters  $X, Y, Z$  (possibly with indices) always denote sets; the cardinality of a set  $X$  is denoted by  $|X|$ . A cardinality will be called **attainable** if it is smaller than the first unattainable (in the strong sense) cardinality.

If  $R \subset X \times X$ , then the pair  $(R, X)$  (and sometimes also  $R$  itself) is called a **relation** on  $X$ ; the relation  $(R, X)$  is called **reflexive, symmetric**, etc., if  $R$  has the corresponding property in the usual sense. Instead of  $(x, y) \in R$  one sometimes writes  $xRy$ . A mapping  $f : X \rightarrow Y$ , carrying  $X$  into a subset of  $Y$ , is understood as a triple  $(\varphi, X, Y)$ , where  $\varphi \subset Y \times X$  satisfies the well-known conditions; for brevity, sometimes no distinction is made in notation between  $f$  and

$$\varphi = \{(f(x), x) \mid x \in X\}.$$

If there are relations  $(R, X)$ ,  $(S, Y)$  and a mapping  $f : X \rightarrow Y$ , then  $f$  is called  **$RS$ -admissible** if  $xRx'$  implies  $f(x)Sf(x')$ , i.e. if  $f \circ R \subset S \circ f$  in the sense of composition of relations, and **strongly admissible** if  $f \circ R = S \circ f$ .

If  $(R, X)$  is a relation, then  $C(R, X)$  and, respectively,  $C^*(R, X)$  denotes the semigroup of all  $RR$ -admissible (respectively strongly admissible) mappings; obviously, this is a semigroup with identity. The relation  $(R, X)$  is called **invertible** if  $C(R, X)$  is a group with identity.

By  $\mathfrak{R}$  (respectively  $\mathfrak{R}^*$ ) is denoted the category whose objects are relations  $(R, X)$ , and whose morphisms from  $(R, X)$  to  $(S, Y)$  are the  $RS$ -admissible (respectively strongly  $RS$ -admissible) mappings;  $\mathfrak{R}$  may also be regarded as the category of directed graphs, with the morphisms being mappings that carry edges into edges. By  $\mathfrak{R}_a$  is denoted the full subcategory of  $\mathfrak{R}$  whose objects are the antireflexive  $(R, X)$ ; by  $\mathfrak{R}_t$ , the full subcategory of  $\mathfrak{R}^*$  whose objects are transitive antireflexive antisymmetric relations. If  $A$  is a set, then by  $A\mathfrak{R}$  is denoted the following category: the objects are families of relations of the form  $\{(R_a, X); a \in A\}$ ; the morphisms from  $\{(R_a, X); a \in A\}$  to  $\{(S_a, Y); a \in A\}$  are those  $f : X \rightarrow Y$  which are  $R_{aS}a$ -admissible for every  $a \in A$ . Obviously, if  $|A| = 1$ , then  $A\mathfrak{R}$  is isomorphic to  $\mathfrak{R}$ . By  $\mathfrak{S}_0(l)$  will be denoted the category of

$T_0$ -topological spaces, whose morphisms are taken to be local homeomorphisms (onto a space).

Let  $\mathfrak{K}$  be a category. If the class  $\mathfrak{K}'$  of its morphisms is a set, then  $\mathfrak{K}$  will be called a **small category**; the cardinality of  $\mathfrak{K}'$  will be denoted by  $|\mathfrak{K}'|$ .

Let  $\mathfrak{K}$  and  $\Omega$  be categories. We shall say that the category  $\Omega$  is **representable** in  $\mathfrak{K}$  if it is isomorphic to a full subcategory of  $\mathfrak{K}$ .

Finally, let us introduce abbreviated notation for the following assertions (in which  $\mathfrak{a}$  is a cardinality):  $\mathcal{F}(\mathfrak{a})$ : there exists an invertible  $(R, X)$  such that  $|X| \geq \mathfrak{a}$ ;  $\mathcal{M}(\mathfrak{a})$ : for every family of relations

$\{(R_{aX}) : a \in A\}$ ,  $|A| \leq \mathfrak{a}$ , there exists a relation  $(R, Y)$  such that the semigroups  $C(R, Y)$  and  $\bigcap \{C(R_a, X) \mid a \in A\}$  are isomorphic;  $\mathfrak{R}(\mathfrak{a})$ : if  $|A| \leq \mathfrak{a}$ , then  $A\mathfrak{R}$  is representable in  $\mathfrak{K}$ .

## 2. Basic constructions.

For a given relation  $(R, X)$  or family of relations  $\{(R_a, X)\}$ , relations  $R^{(1)}, R^{(2)}, R^{(3)}$  are constructed (in an essentially unique way).

- 1) Let  $(R, X)$  be a relation on the set  $X$ . Put  $X^{(1)} = X \cup R \cup U$ ,  $U = \{u_1^1, u_2^1, u_1^2, u_2^2, u_3^2\}$ . On the set  $X^{(1)}$  define the relation  $R^{(1)}$  as follows:  $u_1^1 R^{(1)} u_2^1$ ;  $u_i^2 R^{(1)} u_{i+1}^2$ ,  $i = 1, 2$ ;  $u_2^1 R^{(1)} u_1^1$ ;  $u_3^2 R^{(1)} u_2^2$ ; for every  $x \in X$  and  $i = 1, 2$ ,  $u_i^{R^{(1)}} x$ ; for every  $(x, y) \in R$ ,  $xR^{(1)}(x, y)$ ,  $(x, y)R^{(1)}y$ .
- 2) Let  $(S_i, Y_i)$  ( $i = 1, 2$ ) be relations,  $A$  a set,  $\varphi_i : A \rightarrow Y_i$  ( $i = 1, 2$ ) mappings such that there exist  $y_i^0 \in Y_i \setminus \varphi_i(A)$ ; let  $j_1, \dots, j_4$  be natural numbers,  $U_k = \{u_k(1), u_k(2), \dots, u_k(j_k)\}$ ,  $U = U_1 \cup U_2 \cup U_3 \cup U_4$ . Suppose  $\{(R_{aX}), a \in A\}$  is a family of relations on  $X$ . Then we put  $Z = \{(x, x', a) \mid xR'_{ax}, x, x' \in X\}$ ,  $X^{(2)} = X \cup Y_1 \cup Y_2 \cup Z \cup U$ , and define on the set  $X^{(2)}$  the relation  $R^{(2)}$  as follows:

$$\begin{aligned} u_k(i)R^{(2)}u_k(i+1), & \quad k = 1, 2, 3, 4, \quad i = 1, 2, \dots, j_k - 1; \\ u_k(j_k)R^{(2)}u_k(1), & \quad k = 1, 2, 3, 4; \\ u_k(1)R^{(2)}y_i, & \quad y_i \in Y_i, \quad i = 1, 2, \quad k = i, i + 2; \end{aligned}$$

for every  $x \in X$ ,  $i = 1, 2$ ,  $y_i^0 R^{(2)}x$ ; for every  $(x, x', a) \in Z$ ,  $i = 1, 2$ ,  $\varphi_i(a)R^{(2)}(x, x', a)$ ; for every  $(x, x', a) \in Z$ ,  $xR^{(2)}(x, x', a)$  and  $(x, x', a)R^{(2)}x'$ ; for  $y_i, y'_i \in Y_i$ ,  $y_i R^{(2)} y'_i$  holds if and only if  $y_i S_{iy} i'$ .

- 3) Let  $(R, X)$  be a relation. Let  $V = \{(x, y, i) \mid i = 1, 2; xRy\}$ . Put  $X^{(3)} = X \cup V$  and define  $R^{(3)}$  on the set  $X^{(3)}$  as follows:  $(x, y, 1)R^{(3)}x$ ,  $(x, y, 1)R^{(3)}y$ ,  $(x, y, 1)R^{(3)}(x, y, 2)$ ,  $(x, y, 2)R^{(3)}y$ .

**Proposition 1.** If  $(R, X)$  is antireflexive, then  $C(R, X)$  is isomorphic to  $C(R^{(1)}, X^{(1)})$ ; moreover,  $(R^{(1)}, X^{(1)})$  has no cycles of odd length not divisible by 3.

A **cycle of length**  $m$  for a relation  $(S, Y)$  is a sequence  $x_1, x_2, \dots, x_n$  such that  $x_i S x_{i+1}, x_n S x_1$ .

**Proposition 2.** Let  $(S_1, Y_1), (S_2, Y_2)$  be discretized relations, and let there be distinct prime numbers  $j_1, j_2, j_3, j_4$  such that  $(S_i, Y_i)$  has no cycle of length  $j_k$  ( $i = 1, 2; k = 1, \dots, 4$ ). Let  $\varphi_i$  ( $i = 1, 2$ ) be a one-to-one mapping of the set  $A$  into  $Y_i$ , with  $\varphi_i[A] \neq Y_i$ . Suppose a family of relations  $\{(R_a, X), a \in A\}$  is given such that for some  $a$  we have  $R_a = \{(x, x) \mid x \in X\}$ . Then, for  $X^{(2)}, R^{(2)}$  defined above, the subsemigroup  $C(R^{(2)}, X^{(2)})$  is isomorphic to  $\bigcap \{C(R_a, X) \mid a \in A\}$ .

**Proposition 3.** If  $(R, X)$  is antireflexive, then the semigroup  $C[R, X]$  is isomorphic to  $C_*[R^{(3)}, X^{(3)}]$ .

### 3.

The main result of the paper is the following assertion:

**Theorem 1.** If  $\mathfrak{a}$  is an attainable cardinal,  $\mathfrak{K}$  a small category,  $|\mathfrak{K}| \leq \mathfrak{a}$ , then  $\mathfrak{K}$  is representable in each of the categories  $\mathfrak{R}, \mathfrak{R}_*, \mathfrak{R}_a, \mathfrak{R}_{f*}, \mathfrak{T}_0(l)$ .

More generally, the following holds:

**Theorem 2.** Suppose that for the cardinal  $\mathfrak{a}$  the condition  $\mathcal{F}(\mathfrak{a})$  holds. Then every small category  $\mathfrak{K}$  such that  $|\mathfrak{K}| \leq \mathfrak{a}$  is representable in  $\mathfrak{R}_a, \mathfrak{R}_*^*, \mathfrak{T}_0(l)$ .

These theorems follow from the following assertions:

**Theorem 3.** Every small category  $\mathfrak{K}$  is representable in the category  $A\mathfrak{R}$ , and as  $A$  one may take the set of morphisms of the category  $\mathfrak{K}$ .

**Proof.** Denote by  $K$  the set of objects of the category  $\mathfrak{K}$ , and by  $M(a, b)$  the set of morphisms from the object  $a$  to the object  $b$ . Put  $T(a) = (\bigcup \{M(b, a) \mid b \in K\}; \{R_\alpha\}, \alpha \in \mathfrak{K}')$ , where  $\beta R_\alpha \gamma \iff \beta = \gamma \circ \alpha; T(\beta) = \{\gamma \mapsto \beta \circ \gamma\}$ . It is easy to verify that this defines a mutu-

has a unique functor in  $A\mathfrak{R}$ . It remains to show that for every morphism  $f : T(a) \rightarrow T(b)$  there exists  $\varphi \in M(a, b)$ ,  $f = T(\varphi)$ . Let  $\varepsilon$  be the identity morphism of the object  $b$ . Since  $a = \varepsilon \circ a$ , it follows that  $a R_\alpha \varepsilon$  and, consequently,  $f(a) R_{\alpha f}(\varepsilon)$ , or, by the definition of  $R_\alpha$ ,  $f(a) = f(\varepsilon) \circ a$ . Hence  $f = T(f(\varepsilon))$ .

**Theorem 4.** Let  $\mathcal{F}(|A|)$  hold. Then  $A\mathfrak{R}$  is representable in  $\mathfrak{R}_a$ .

**Proof.** Let  $(S_i, Y_i), i = 1, 2$ , be marked relations,  $|Y_i| \geq |A|$ . We may assume  $|Y_i| > 1$ ; then the  $S_i$  are antireflexive. According to Proposition 1, there are distinct primes  $j_1, \dots, j_4$  such that  $Y_i$  has no cycles of length  $j_k$ . We now carry out construction 2) for each object of the category  $A\mathfrak{R}$ , each time with the same  $(S_1, Y_1), (S_2, Y_2)$ . It can be shown that the morphisms of the category  $A\mathfrak{R}$  are put in one-to-one correspondence with the morphisms of the objects of the

category  $\mathfrak{R}$  obtained in the indicated way; more precisely, every morphism from  $\{(R_a, X); a \in A\}$  to  $\{(\overline{R}_a, \overline{X}); a \in A\}$  is extended uniquely to a morphism from  $(R^{(2)}, X^{(2)})$  to  $(\overline{R}^{(2)}, \overline{X}^{(2)})$ , and conversely, every morphism from  $(R^{(2)}, X^{(2)})$  to  $(\overline{R}^{(2)}, \overline{X}^{(2)})$  induces, for each  $a \in A$ , an  $R_a \overline{R}_a$ -admissible mapping.

**Remark.** As a consequence, we obtain the following equivalence of statements:

$$\mathcal{F}(a) \iff \mathcal{M}(a) \iff \mathcal{K}(a).$$

**Theorem 5.** *The category  $\mathfrak{R}_a$  is representable in  $\mathfrak{R}_t^*$ .*

The proof is not difficult to give, using construction 3).

From Theorems 3 and 4, Theorem 2 follows directly. The assertion about the category  $\mathfrak{L}_0(l)$  can be obtained by means of a modification of the result on  $\mathfrak{R}_t^*$ . Theorem 1 is a consequence of Theorem 2 and of the fact that, for attainable cardinal numbers, the assertion  $\mathcal{F}(a)$  holds.

Let us note that, according to a personal communication from P. Vopěnka,  $\mathcal{F}(a)$  holds even for some further cardinalities (of course, under the assumption of their existence).

**Additional remarks.** In particular, Theorems 1 and 2 can be applied to semigroups with identity. We obtain the assertion: every semigroup with identity and of attainable cardinality is isomorphic to some  $C(R, X)$  and to some  $C^*(S, Y)$ .

By definition,

$$C(R, X) = \{f \mid f \circ R \subset R \circ f\}, \quad C^*(R, X) = \{f \mid f \circ R = R \circ f\}.$$

In this connection, at first sight the question of representing semigroups in one of the following ways seems interesting (capital letters denote relations, and lowercase letters mappings):

- A.  $\{f \mid f \circ g \subset g \circ f\}$ , in other words,  $\{f \mid f \circ g = g \circ f\}$ .
- B.  $\{S \mid S \circ f \subset f \circ S\}$ .
- C.  $\{S \mid S \circ f = f \circ S\}$ .
- D.  $\{S \mid S \circ R \subset R \circ S\}$ .
- E.  $\{S \mid S \circ R = R \circ S\}$ .

The answer, however, is negative, since even the permutation group of a set consisting of three elements cannot be represented in any of the ways A-E.
