**ON SOLVING THE DIRICHLET PROBLEM  
BY THE METHOD OF REFINEMENTS US-  
ING DIFFERENCES OF HIGHER ORDERS**

*(Presented by Academician A. N. Kolmogorov on 24 II 1965)*

In the present paper, the estimates of the irregular component of the error in the solution of the Dirichlet problem for the Poisson (Laplace) equation, obtained by the method of refinements using differences of higher orders, are substantially improved in two cases: when the domain has a smooth boundary (see <sup>(1,2)</sup>) or is a rectangle (see <sup>(3)</sup>). In addition, an example is given establishing the erroneous-ness of a theorem of V. S. Korolyuk <sup>(4,5)</sup> concerning the method of refinements using differences of higher orders.

1. Consider the boundary-value problem

$$\Delta u = f \quad \text{in } R; \quad u = \varphi_j \quad \text{on } \Gamma_j, \quad j = 1, 2, 3, 4, \quad (1)$$

where  $R$  is the rectangle  $\{0 < x < a, 0 < y < b\}$ ;  $\Gamma_j$  are the sides of the rectangle, including the endpoints. Suppose that

$$f \in C_{2m,\lambda}(\overline{R})^*, \quad \varphi_j \in C_{2m+2,\lambda}(\Gamma_j), \quad j = 1, 2, 3, 4, \quad (2)$$

where  $m \geq 1$ ,  $0 < \lambda < 1$ , and, in addition,

$$f_{x^{2p}y^{2q}}^{(2p+2q)}(x_j, y_j) = 0, \quad 0 \leq p + q \leq m, \quad j = 1, 2, 3, 4,$$

$$\varphi_j^{(2k)}(s_{j1}) = \varphi_j^{(2k)}(s_{j2}) = 0, \quad 0 \leq k \leq m + 1, \quad j = 1, 2, 3, 4, \quad (3)$$

where  $(x_j, y_j)$  are the coordinates of the vertices of  $\overline{R}$ ;  $s_{j1}$  and  $s_{j2}$  are the beginning and end of  $\Gamma_j$ .\*\* Under these assumptions, the solution of problem (1) satisfies  $u \in C_{2m+2,\lambda}(\overline{R})$  (see <sup>(7)</sup>). Let  $a/h$  and  $b/h$  be integers,  $h \leq \min\{a, b\}/(2m + 2)$ . Construct a grid of the straight lines  $x, y = 0, h, 2h, \dots$  and denote by  $R_h$  the set of grid nodes belonging to  $R$ , and by  $\Gamma_{jh}$  the set of nodes lying on  $\Gamma_j$ . Introduce the averaging operator  $A$

$$Au(x, y) = (u(x + h, y) + u(x - h, y) + u(x, y + h) + u(x, y - h))/4$$

and consider the recurrent sequence of systems of difference equations

$$u^q = \varphi_j \quad \text{on } \Gamma_{jh}, \quad j = 1, 2, 3, 4, \quad (5)$$

$$u^q = Au^q - h^2 f/4 - D^{(m)}u^{q-1} \quad \text{on } R_h, \quad (4)$$

where  $q = 1, 2, \dots, m + 1$ ;  $u^0 \equiv 0$ ;  $D^{(m)}$  is a linear difference operator of order  $2m + 2$ , which, upon substituting the functions  $u^q$  and  $u^{q-1}$  into equations (4), gives residuals of order  $h^{2m+2+\lambda}$ . The operator  $D^{(m)}$ , at all nodes where possible, is expressed in terms of operators for computing central differences, while at the remaining nodes the operator  $D^{(m)}$  is constructed using Newton's interpolation formula (see (2)).

\* Definition of the class  $C_{k,\lambda}$  see, for example, in (6).

\*\* If (2) holds but (3) is not fulfilled, then from the solution of problem (1) one subtracts

a certain elementary function, and for the remaining term conditions of the form (2) and (3) are satisfied (see (3)).

**Theorem 1.** If (2)–(3) hold, then the solutions  $u^q$ ,  $q = 1, 2, \dots, m + 1$ , of the systems of difference equations (4)–(5) are representable on  $R_h$  in the form

$$u^q = u + \sum_{k=q}^m h^{2k} w_k^q + h^{2m+\lambda} r^q, \quad (6)$$

where  $u$  is the solution of problem (1);  $w_k^q$  are the traces on  $R_h$  of certain functions  $w_k^q(x, y) \in C_{2m+2-2k,\lambda}(\bar{R})$ , independent of  $h$ , such that

$$\|w_k^q\|_{C_{2m+2-2k,\lambda}(\bar{R})} \leq c_q \left( \sum_{j=1}^4 \|\varphi_j\|_{C_{2m+2,\lambda}(\Gamma_j)} + \|f\|_{C_{2m,\lambda}(\bar{R})} \right)^* ;$$

$r^q$  are certain functions defined on  $R_h$  such that

$$\max_{R_h} |r^q| \leq c_q \left( \sum_{j=1}^4 \|\varphi_j\|_{C_{2m+2,\lambda}(\Gamma_j)} + \|f\|_{C_{2m,\lambda}(\bar{R})} \right).$$

Theorem 1 establishes that, in the case of a rectangle, the irregular component of the error of the approximate solution  $u^q$  of problem (1) has order  $h^{2m+\lambda}$  for all  $q \leq m + 1$ . The author supposes that the estimate given for the irregular error cannot be improved in order with respect to  $h$ . Theorem 1 refines and improves, for the Dirichlet problem, theorem 1 of (3), according to which the irregular error in  $u^q$  has order  $h^{2m+1-q}$ .

2. Let the boundary-value problem

$$\Delta u = f \quad \text{on } \Omega; \quad u = \varphi \quad \text{on } \gamma, \quad (7)$$

be given, where  $\gamma$  is the boundary of the domain  $\Omega \subset R$ . Denote by:  $\Omega_h$  the set of mesh nodes belonging to  $\Omega$ , and such that their four neighboring nodes also belong to  $\Omega$ ;  $\gamma_h$  the set of the remaining nodes belonging to  $\Omega$ . Introduce on the axis  $\tau$  the operator  $I_\delta^n$

$$I_\delta^n \psi(0) \equiv \sum_{k=1}^n (-1)^{k-1} \frac{n!}{(n-k)! k!} \frac{\delta}{\delta+k} \psi(-k\bar{h})$$

and denote:

$$\lambda_n = \prod_{k=1}^n \frac{k}{\delta+k};$$

$\delta_n$  is the positive root of the equation

$$\sum_{k=1}^n \frac{n!}{(n-k)! k!} \frac{\delta}{\delta+k} = \frac{1}{2}.$$

Suppose that  $\gamma \in {}_{2m+2}(B, \lambda)$  (see (8)),  $m \geq 1$ , and  $h$  is so small that it is possible to write the following recurrent sequence of systems of difference equations:

$$\begin{aligned} u^q &= Au^q - h^2 f/4 - D^{(m)} u^{q-1} && \text{on } \Omega_h, \\ u^q &= I_\delta^{2m} u^q + \lambda_{2m} \varphi && \text{on } \gamma_h, \end{aligned} \quad (8)$$

where the operator  $I_\delta^{2m}$  is constructed with step  $\bar{h} = ([1/\delta_{2m}] + 1)h$ ; the origin of coordinates on the axis  $\tau$  is at the corresponding point  $\gamma_h$ ;  $\delta h$  is the distance from the origin of coordinates to the point of intersection of the axis  $\tau$  with  $\gamma$ , at which the value of  $\varphi$  is taken;  $0 \leq \delta \leq \delta_{2m}$ ; the segment of the axis  $\tau$   $[\delta h, -2m\bar{h}] \subset \Omega$ ;  $u^0 \equiv 0$ .

**Theorem 2.** If  $\gamma \in {}_{2m+2}(B, \lambda)$ ,  $\varphi \in C_{2m+2, \lambda}(\gamma)$ ,  $f \in C_{2m, \lambda}(\bar{\Omega})$ ,  $m \geq 1$ ,  $0 < \lambda < 1$ , then the solutions  $u^q$ ,  $q = 1, 2, \dots, m + 1$ , of the systems of difference equations (8) are representable on  $\Omega_h \cup \gamma_h$  in the form

Fig. 1

Figure 1: Fig. 1

$$u^q = u + \sum_{k=q}^m h^{2k} w_k^q + h^{2m+\lambda} \left( \ln \frac{a+b}{h} \right)^{q-1} r^q, \tag{9}$$

\* Here and below,  $c_p$ ,  $p = 1, 2, \dots$ , denote constants independent of the factor standing to the right and of  $h$ .

where  $u$  is the solution of problem (7),  $w_k^q$  are the traces on  $\Omega_h \cup \gamma_h$  of certain functions, independent of  $h$ ,  $w_k^q(x, y) \in C_{2m+2-2k, \lambda}(\bar{\Omega})$ , such that

$$\|w_k^q\|_{C_{2m+2-2k, \lambda}(\bar{\Omega})} \leq c_q (\|\varphi\|_{C_{2m+2, \lambda}(\gamma)} + \|f\|_{C_{2m, \lambda}(\bar{\Omega})});$$

$r^q$  are certain functions defined on  $\Omega_h \cup \gamma_h$  such that

$$\max_{\Omega_h \cup \gamma_h} |r^q| \leq c_q (\|\varphi\|_{C_{2m+2, \lambda}(\gamma)} + \|f\|_{C_{2m, \lambda}(\bar{\Omega})}).$$

Theorem 2 substantially improves the result of (1, 2), since in (9) the irregular error contains the inessential factor

$$\left( \ln \frac{a+b}{h} \right)^{q-1}$$

instead of the quantity  $h^{2-2q}$  entering into the corresponding estimate given in (1, 2).

**Fig. 1**

3. In (4, 5) the recurrent system of difference equations is considered

$$\begin{aligned} \frac{1}{h^2} \Delta_h u_0 &= f, & \delta_h u_0 &= \varphi, \\ \frac{1}{h^2} \Delta_h u_1 + L_1(u_0) &= 0, & \delta_h u_1 &= \delta_1(u_0), \\ & \dots\dots\dots & & \\ \frac{1}{h^2} \Delta_h u_{q-1} + L_1(u_{q-2}) + \dots + L_{q-1}(u_0) &= 0, & \delta_h u_{q-1} &= \delta_1(u_{q-2}) + \dots + \delta_{q-1}(u_0), \end{aligned} \tag{10}$$

where  $\Delta_h, L_k$  are certain difference operators defined on  $\Omega_h$ ;

$\Delta_h = 4(A - E)$ ;  $Eu \equiv u$ ;  $\delta_h$  is an operator defined on  $\gamma_h$  such that, for a sufficiently smooth solution of problem (7),

$$\delta_h u = \varphi + h^2 \delta_1(u) + \dots + h^{2q-2} \delta_{q-1}(u) + O(h^{2q}); \quad (11)$$

$\delta_1, \delta_2, \dots, \delta_{q-1}$  are certain difference operators.

In (4, 5) the following theorem is formulated (in the author's notation). If  $\gamma \in \Pi_{4q}(B, \lambda)$ ,  $\varphi \in C_{4q, \lambda}(\gamma)$ ,  $f \in C_{4q-2, \lambda}(\bar{\Omega})$ , then the solution  $u$  of problem (7) is representable on  $\Omega_h \cup \gamma_h$  in the form of the asymptotic series

$$u = u_0 + h^2 u_1 + \dots + h^{2q-2} u_{q-1} + O(h^{2q}), \quad (12)$$

where  $u_0, u_1, \dots, u_{q-1}$  are the solutions of the system of difference equations (10).

The incorrectness of the proof in (5) of this theorem was noted in (9). We give an example establishing the erroneous nature of the theorem. Let  $\gamma$  contain the rectilinear segment  $KM$ , intersecting at a small angle  $\theta > 0$  the vertical line of the grid at the point  $T$ , located midway between the nodes 4 and 9 (Fig. 1). This arrangement of the points 1, 2, ..., 12 takes place if  $a = 2b$ ;  $T$  lies at the center  $R$ ;  $h = b/(2k + 1)$ , where  $k$  is any integer exceeding a certain constant. Let also  $\gamma \in \Pi_8(B, \lambda)$ ,  $f = 4$ , and the function  $\varphi$  be such that  $u = x^2 + y^2$  in  $\Omega$ . According to (11), take the following expressions for  $\delta_h u$  and  $\delta_1(u)$  at point 4:

$$\delta_h u = u^4(1 + \delta) - u^5 \delta, \quad (13)$$

$$\delta_1(u) = \delta(-u^4(5+6\delta+\delta^2)/6 + u^5(4+5\delta+\delta^2)/2 - u^6(3+4\delta+\delta^2)/2 + u^7(2+3\delta+\delta^2)/6)/h^2, \quad (14)$$

where  $\delta$  is a parameter such that  $\delta h$  is equal to the distance between the points 4 and 4';  $u^k$  is the value of  $u$  at the  $k$ -th point. The function  $w = u_0 - u$  satisfies the system of difference equations

$$\Delta_h w = 0, \quad \delta_h w = \delta(1 + \delta)h^2, \quad (15)$$

where  $\delta$  is the parameter on  $\gamma_h$  (see (13)). Let  $0 \leq \delta < 1$ . Then

$$0 \leq w < 2h^2 \quad \text{on } \Omega_h \cup \gamma_h. \quad (16)$$

Since at point 4  $\delta = \varepsilon$ , and at point 10  $\delta = 1 - \varepsilon$ , where  $\varepsilon = (\text{tg } \theta)/2$ , it follows, according to (13), (15), (16), that

$$w^4 < \varepsilon \cdot 3h^2, \quad (17)$$

$$w^{10} = (1 - \varepsilon)h^2 + w^{11}(1 - \varepsilon)/(2 - \varepsilon) * . \quad (18)$$

Taking (15)–(18) into account, it is not difficult to calculate that for  $\varepsilon \leq 10^{-3}$  at point 4  $\delta_1(w) > \varepsilon/20$ . Let  $\bar{w} = u_0 + h^2 u_1 - u$ . Since  $\delta_h \bar{w} = h^2 \delta_1(w)$ , it follows from what has been said and from (13) that for  $\varepsilon = \varepsilon_0 = 10^{-3}$   $\max\{\bar{w}^4, |\bar{w}^5|\} > \varepsilon_0 h^2/50$ , which contradicts the theorem cited above (<sup>4</sup>, <sup>5</sup>), according to which  $\bar{w} = O(h^4)$ .

V. S. Korolyuk pursued the aim of simplifying the method of refinement by differences of higher orders by using in the system of difference equations (10) the simple operator  $\delta_h$  (instead of  $I_\delta^{2m}$ ) and by introducing, both on  $\Omega_h$  and on  $\gamma_h$ , corrections through the preceding solution by means of difference operators whose accuracy increases gradually from refinement to refinement, and is not fixed in advance. But, as the example shows, such a scheme as a whole, generally speaking, does not lead to the desired result. V. S. Korolyuk's proposal on the gradual complication of the difference operators calculating the corrections can possibly be realized only at interior nodes, and even then, apparently, not at all of them. At nodes close to  $\gamma_h$ , where operators calculating central differences cannot be applied, it will evidently be necessary to use operators of order  $2m$ , and these operators will depend on  $q$ .

A detailed analysis of the question is being published in (<sup>10</sup>).
