**SOME ASYMPTOTIC FORMULAS FOR THE SPECTRA OF THE THIRD BOUNDARY-VALUE PROBLEM RELATED TO VARIATION OF THE FUNCTION ENTERING THE BOUNDARY CONDITION**

*(Presented by Academician L. V. Kantorovich on 25 VIII 1966)*

Let  $V$  be a bounded domain in three-dimensional space, and let  $S$  be its boundary. Further, let  $\{\mu_k(\sigma)\}$  ( $\mu_1(\sigma) \leq \mu_2(\sigma) \leq \dots$ ) be the eigenvalues of the operator  $Lu$ , generated by the operation  $-\Delta u$  under the boundary condition

$$[\partial u / \partial n + \sigma u]_S = 0,$$

where  $\partial u / \partial n$  is differentiation in the direction of the outward normal.

It is known (see (1)) that

$$\mu_n(\sigma) \sim (6\pi^2 v^{-1} n)^{2/3} \quad (n \rightarrow \infty) \tag{1}$$

( $v$  is the volume of the domain  $V$ ); from this it is not difficult to derive the relation

$$\sum_{\mu_k(\sigma) \leq x} \mu_k(\sigma_1) \sim \frac{v}{10\pi^2} x^{5/2} \quad (x \rightarrow +\infty),$$

where  $\sigma(Q)$  and  $\sigma_1(Q)$  ( $Q \in S$ ) are two, generally speaking, different functions (the summation extends over all values of  $k$  for which  $\mu_k(\sigma) \leq x$ ).

In this note the asymptotic behavior of the difference

$$\sum_{\mu_k(\sigma) \leq x} \mu_k(\sigma_2) - \sum_{\mu_k(\sigma) \leq x} \mu_k(\sigma_1);$$

is studied; namely, the equality

$$\sum_{\mu_k(\sigma) \leq x} [\mu_k(\sigma_2) - \mu_k(\sigma_1)] = \frac{1}{3\pi^2} \int_S [\sigma_2(Q) - \sigma_1(Q)] ds \cdot x^{3/2} + o(x^{3/2}) \quad (x \rightarrow +\infty). \tag{2}$$

is established.

Some of its generalizations are also given.

Formula (2) may be regarded as a generalization to the three-dimensional case of the well-known formula of I. M. Gelfand and B. M. Levitan for the difference of the traces of two Sturm-Liouville operators (see (2)).

Let  $Q$  be an arbitrary point of the surface  $S$ . We shall assume that some neighborhood of this point on the surface  $S$  can be given by the equation  $z = z_Q(x, y)$  (the  $z$ -axis is directed along the normal to  $S$  at the point  $Q$ ), and that the function  $z_Q(x, y)$  everywhere in the disk  $x^2 + y^2 < \rho_0^2$  (where  $\rho_0$  does not depend on  $Q$ ) has second partial derivatives satisfying a Lipschitz condition (with exponent equal to 1 and with a constant independent of  $Q$ ).

**Theorem 1.** *If the function  $\sigma(Q)$  satisfies a Lipschitz condition, then as  $p \rightarrow +\infty$*

$$\sum_{k=1}^{\infty} \frac{1}{[\mu_k(\sigma) + p]^2} = \frac{v}{8\pi} \frac{1}{\sqrt{p}} + \frac{s}{16\pi} \frac{1}{p} + \frac{1}{24\pi} \int_S [h(Q) - 3\sigma(Q)] ds \frac{1}{p^{3/2}} + O\left(\frac{1}{p^2}\right), \quad (3)$$

where  $v$  and  $s$  are the volume of the domain  $V$  and the area of the surface  $S$ ;  $h(Q)$  is the mean curvature of the surface  $S$  at the point  $Q$ .

**Proof.** Let  $G(M, M_1, -\chi^2) = (4\pi r_{MM_1})^{-1} e^{-\chi r_{MM_1}} - g(M, M_1, \chi)$  be the Green's function of the expression  $\Delta u - \chi^2 u$  ( $\chi$  is a sufficiently large positive constant) for the domain  $V$  under the boundary condition  $[\partial u / \partial n + \sigma u]_S = 0$ . As  $M_1 \rightarrow M$ , from the equality

$$G(M, M_1, -\chi_1^2) - G(M, M_1, -\chi^2) = (\chi^2 - \chi_1^2) \sum_{k=1}^{\infty} \frac{u_k(M) u_k(M_1)}{[\mu_k(\sigma) + \chi_1^2][\mu_k(\sigma) + \chi^2]},$$

where  $\{u_k(M)\}$  are the eigenfunctions of the operator  $Lu$ , and  $\chi_1 \neq \chi$ , it follows that

$$\frac{\chi_1 - \chi}{4\pi} + g(M, M, \chi_1) - g(M, M, \chi) = (\chi_1^2 - \chi^2) \sum_{k=1}^{\infty} \frac{u_k^2(M)}{[\mu_k(\sigma) + \chi_1^2][\mu_k(\sigma) + \chi^2]}.$$

Hence follows the formula

$$\sum_{k=1}^{\infty} \frac{1}{[\mu_k(\sigma) + \chi^2]^2} = \frac{v}{8\pi} \frac{1}{\chi} + \frac{1}{2\chi} \int_V g'_\chi(M, M, \chi) dv_M.$$

By means of a method close to that used in (3), it can be proved that

$$\int_V g'_\chi(M, M, \chi) dv_M =$$

$$= \frac{s}{8\pi} \frac{1}{\chi} + \frac{1}{12\pi} \int_S [h(Q) - 3\sigma(Q)] ds \cdot \frac{1}{\chi^2} + O\left(\frac{1}{\chi^3}\right) \quad (\chi \rightarrow +\infty).$$

Combining the last two equalities and putting  $\chi^2 = p$ , we obtain (3).

**Theorem 2.** Let  $\sigma(Q)$ ,  $\sigma_1(Q)$ , and  $\sigma_2(Q)$  ( $Q \in S$ ) be any three functions satisfying the Lipschitz condition. Then

$$\sum_{\mu_k(\sigma_2) \leq x} [\mu_k(\sigma_2) - \mu_k(\sigma_1)] = \frac{I}{3\pi^2} x^{3/2} + O(x^{3/2}) \quad (x \rightarrow +\infty), \quad (4)$$

where

$$I = \int_S [\sigma_2(Q) - \sigma_1(Q)] ds.$$

**Proof.** Suppose first that  $\sigma_2(Q) \geq \sigma_1(Q)$ . Introduce for consideration the nonnegative and nondecreasing function

$$\Phi(x) = \sum_{\mu_k(\sigma_2) \leq x} [\mu_k(\sigma_2) - \mu_k(\sigma_1)];$$

moreover, set

$$\psi(p) = \sum_{k=1}^{\infty} \frac{[\mu_k(\sigma_2) - \mu_k(\sigma_1)]^2 [\mu_k(\sigma_2) + 2\mu_k(\sigma_1) + 3p]}{[\mu_k(\sigma_2) + p]^3 [\mu_k(\sigma_1) + p]^2}.$$

We now use Theorem 1: let us write formula (4) first for the function  $\sigma_1(Q)$ , and then for the function  $\sigma_2(Q)$ ; subtracting the second from the first equality, we find that for any  $\alpha < \mu_1(\sigma_2)$

$$2 \int_{\alpha}^{+\infty} \frac{d\Phi(x)}{(x+p)^3} + \psi(p) = \frac{I}{8\pi} \frac{1}{p^{3/2}} + O\left(\frac{1}{p^2}\right) \quad (p \rightarrow +\infty).$$

Taking further into account that

$$\psi(p) = o\left[\int_{\alpha}^{+\infty} (x+p)^{-3} d\Phi(x)\right] \quad \text{as } p \rightarrow +\infty,$$

we have

$$\int_{\alpha}^{+\infty} \frac{d\Phi(x)}{(x+p)^3} \sim \frac{I}{16\pi} \frac{1}{p^{3/2}} \quad (p \rightarrow +\infty).$$

Applying the Hardy-Littlewood Tauberian theorem (see, for example, (4)), we find:

$$\Phi(x) = \sum_{\mu_k(\sigma_2) \leq x} [\mu_k(\sigma_2) - \mu_k(\sigma_1)] \sim \frac{I}{3\pi^2} x^{3/2} \quad (x \rightarrow +\infty).$$

Similarly, the asymptotic equality is established

$$\sum_{\mu_k(\sigma_1) \leq x} [\mu_k(\sigma_2) - \mu_k(\sigma_1)] \sim \frac{I}{3\pi^2} x^{3/2} \quad (x \rightarrow +\infty).$$

Taking further into account that

$$\sum_{\mu_k(\bar{\sigma}) \leq x} [\mu_k(\sigma_2) - \mu_k(\sigma_1)] \leq \sum_{\mu_k(\sigma) \leq x} \leq \sum_{\mu_k(\underline{\sigma}) \leq x},$$

where  $\bar{\sigma}(Q) = \max\{\sigma(Q), \sigma_2(Q)\}$ ,  $\underline{\sigma}(Q) = \min\{\sigma(Q), \sigma_1(Q)\}$ , and that as  $x \rightarrow +\infty$  the functions

$$\begin{aligned} & \sum_{\mu_k(\bar{\sigma}) \leq x} [\mu_k(\sigma_2) - \mu_k(\sigma_1)] = \\ &= \sum_{\mu_k(\bar{\sigma}) \leq x} [\mu_k(\bar{\sigma}) - \mu_k(\sigma_1)] - \sum_{\mu_k(\bar{\sigma}) \leq x} [\mu_k(\bar{\sigma}) - \mu_k(\sigma_2)], \\ & \sum_{\mu_k(\underline{\sigma}) \leq x} [\mu_k(\sigma_2) - \mu_k(\sigma_1)] \end{aligned}$$

are asymptotically equal to  $\frac{I}{3\pi^2} x^{3/2}$ , we obtain (4) for the special case  $\sigma_2(Q) \geq \sigma_1(Q)$ .

To prove the theorem in the general case, it is now enough to apply the equality

$$\sum_{\mu_k(\sigma) \leq x} [\mu_k(\sigma_2) - \mu_k(\sigma_1)] = \sum_{\mu_k(\sigma) \leq x} [\mu_k(\sigma_0) - \mu_k(\sigma_1)] - \sum_{\mu_k(\sigma) \leq x} [\mu_k(\sigma_0) - \mu_k(\sigma_2)],$$

where  $\sigma_0(Q) = \max\{\sigma_1(Q), \sigma_2(Q)\}$ , and to use the special case of this theorem considered above.

Taking (1) into account, we obtain

**Corollary 1.** As  $n \rightarrow \infty$ ,

$$\sum_{k=1}^n [\mu_k(\sigma_2) - \mu_k(\sigma_1)] = \frac{2I}{v} n + o(n).$$

**Remark.** From Theorem 2 (or Corollary 1) it follows that if the integral

$$I = \int_S [\sigma_2(Q) - \sigma_1(Q)] ds \neq 0,$$

then for infinitely many values of the index  $k$  the difference  $\mu_k(\sigma_2) - \mu_k(\sigma_1)$  has the same sign as the integral  $I$ .

With the aid of Theorem 2, the following can easily be proved.

**Theorem 3.** Let the functions  $\sigma(Q)$ ,  $\sigma_1(Q)$ ,  $\sigma_2(Q)$  and the quantity  $I$  be the same as in Theorem 2. Suppose, further, that on the half-axis  $[a, +\infty)$  there is given a sign-definite function  $f(x)$ , absolutely continuous on every interval  $[a, b]$  ( $b < +\infty$ ); in addition, assume that the expression  $xf'(x)[f(x)]^{-1}$  is bounded almost everywhere and

$$\int^{+\infty} x^{1/2} f(x) dx = \infty.$$

Then, as  $x \rightarrow +\infty$ ,

$$\sum_{a < \mu_k(\sigma) \leq x} f[\mu_k(\sigma)] [\mu_k(\sigma_2) - \mu_k(\sigma_1)] = \left( \frac{I}{2\pi^2} + o(1) \right) \int_a^x |t|^{1/2} f(t) dt.$$

Assuming that  $f(x) = x^m$  ( $m \geq -3/2$ ), we obtain

**Corollary 2.** As  $x \rightarrow +\infty$ ,

$$\sum_{0 < \mu_k(\sigma) \leq x} \mu_k^m(\sigma) [\mu_k(\sigma_2) - \mu_k(\sigma_1)] = \begin{cases} \frac{I}{(2m+3)\pi^2} x^{m+3/2} + o(x^{m+3/2}), & (m > -3/2), \\ \frac{I}{2\pi^2} \ln x + o(\ln x), & (m = -3/2). \end{cases}$$

From Corollary 2 it is not difficult to derive the following assertions:

**A.** If  $\mu_k(\sigma_1) \neq 0$ , then as  $n \rightarrow \infty$

$$\sum_{k=1}^n \frac{\mu_k(\sigma_2)}{\mu_k(\sigma_1)} = n + \left( \frac{6}{\pi^2 \nu} \right)^{1/3} I n^{1/3} + o(n^{1/3}).$$

**B.** If  $\mu_1(\sigma_1) > 0$  and  $\mu_1(\sigma_2) > 0$ , then as  $n \rightarrow \infty$

$$\sum_{k=1}^n [\mu_k^m(\sigma_2) - \mu_k^m(\sigma_1)] =$$

$$= \begin{cases} \frac{m}{(2m+1)\pi^2} \left(\frac{6\pi^2}{2}\right)^{(2m+1)/3} In^{(2m+1)/3} + o(n^{(2m+1)/3}), & (m > -1/2), \\ -\frac{I}{6\pi^2} \ln n + o(\ln n), & (m = -1/2). \end{cases}$$
