## ON FACTOR REPRESENTATIONS OF TYPE $\Pi_1$ FOR THE CLIFFORD ALGEBRA

*(Presented by Academician I. M. Vinogradov on VI 6, 1966)*

**1. A representation of the Clifford (or spinor) algebra with an infinite number of generators** is a set of linear self-adjoint operators  $\{A_k\}_1^\infty$ , acting in a separable Hilbert space  $H$  and satisfying the relations

$$A_k^2 = 1, \quad A_{kA}l + A_{lA}k = 0 \quad (k \neq l). \quad (1)$$

If the weakly closed ring  $M$ , generated by the operators  $\{A_k\}_1^\infty$ , is a factor in the sense of Murray and von Neumann, then such a representation will be called a **factor representation**.

Some properties of factor representations were noted in <sup>(6)</sup>. In the present note we give a complete classification of factor representations of type  $\Pi_1$ , and also consider the question of decomposing a factor representation of type  $\Pi_1$  into irreducible representations.

**2.** Let  $\{A_k\}_1^\infty$  and  $\{B_k\}_1^\infty$  be two factor representations acting in the spaces  $H_1$  and  $H_2$ ; denote the corresponding factors by  $M_1$  and  $M_2$ .

**Definition.** The factor representations  $\{A_k\}_1^\infty$  and  $\{B_k\}_1^\infty$  will be called **algebraically isomorphic** if one can establish an algebraic isomorphism  $\varphi$  between the factors  $M_1$  and  $M_2$  in such a way that  $\varphi(A_k) = B_k$  ( $k = 1, 2, \dots$ ).

It can be shown that there exist algebraically nonisomorphic factor representations of type III and algebraically nonisomorphic representations of type  $\Pi_\infty$ .

**Theorem 1.** *All factor representations of the Clifford algebra of type  $\Pi_1$  are algebraically isomorphic.*

We outline the proof of the theorem. Introduce in the ring  $M_i$  ( $i = 1, 2$ ) a scalar product by putting

$$\langle A, B \rangle = T_i(AB^*),$$

where  $T_i$  is the relative trace for the factor  $M_i$ , and  $A, B \in M_i$ . Then  $M_i$  becomes a pre-Hilbert space. We denote by  $Q(M_i)$  the completion of  $M_i$  with respect to this scalar product. We shall assume that  $T_i(I_i) = 1$ , where  $I_i$  is the identity operator. Consider monomials of the form

$$A_z = A_{s_1} A_{s_2} \cdots A_{s_n},$$

where  $z$  denotes a set of indices  $s_1 < s_2 < \cdots < s_n$ ;  $n = 1, 2, \dots$ ;  $s_i = 1, 2, \dots$  ( $i = 1, 2, \dots, n$ ). It is not difficult to verify that

$$T_1(A_z) = 0$$

for all  $z$ . Consequently, the monomials of the form  $A_z$  and the identity operator  $I_1$  form a complete orthonormal basis in the space  $Q(M_1)$ . Every element  $D$  of  $Q(M_1)$  can be expanded in a series with respect to this basis,

$$D \sim \sum_z d_z A_z \quad \left( \sum_z |d_z|^2 < \infty \right).$$

Now establish a correspondence between  $Q(M_1)$  and  $Q(M_2)$  by the rule

$$\varphi(I_1) = I_2; \quad \varphi(A_z) = B_z.$$

It is not difficult to verify that  $\varphi(C + D) = \varphi(C) + \varphi(D)$  and  $\varphi(C^*) = \varphi(C)^*$ , and if  $C$  and  $D$  belong to  $M_1$  (i.e., are bounded operators), then

$$\varphi(CD) = \varphi(C)\varphi(D).$$

Consequently, if  $C$  is a positive definite operator from  $M_1$ , then  $\varphi(C)$  is also a positive definite operator. But then every operator  $D$  from  $M_1$ , under the mapping  $\varphi$ , falls into  $M_2$ , since the norm of the operator  $\|D\|$  is the least number  $a \geq 0$  for which the operator  $a^2 I_1 - D^* D$  is positive definite. From the considerations given, it follows that  $\varphi(M_1) \subset M_2$ ; similarly we obtain that  $\varphi^{-1}(M_2) \subset M_1$ . Hence,  $\varphi(M_1) = M_2$ .

In <sup>(1)</sup> von Neumann constructed an example of a factor-representation of type  $\text{II}_1$ . From Theorem 1 it follows that all factor-representations of type  $\text{II}_1$  for the Clifford algebra are algebraically isomorphic to this representation.

3. Let us turn to the question of the unitary classification of factor-representations of type  $\text{II}_1$ .

Let  $M$  be a factor of type  $\text{II}_1$ , whose elements act in the space  $H$ . By  $M'$ , as usual, denote the commutant of the factor  $M$ . Let  $f \in H$ ; then by  $H_f^{M'}$  denote the closure of the set  $M'f$  with respect to the norm of  $H$ , and by  $H_f^M$  the closure of  $Mf$ . If  $P_1^f$  is the projector onto  $H_f^{M'}$ , and  $P_2^f$  the projector onto  $H_f^M$ , then

$$T_M(P_1^f) = cT_{M'}(P_2^f),$$

where the constant  $c$  does not depend on  $f$ , and  $T_M$  and  $T_{M'}$  are the traces for  $M$  and  $M'$ , respectively. Introduce for consideration the number <sup>(2)</sup>

$$\theta = T_{M'}(I)/cT_M(I). \quad (2)$$

Under the assumption that  $M$  is a finite factor,  $\theta$  varies in the range  $0 < \theta \leq \infty$ .

**Theorem 2.** *For every number  $\theta$  ( $0 < \theta \leq \infty$ ) there exists a factor-representation of the Clifford algebra of type  $\text{II}_1$ , and this number  $\theta$  determines the factor-representation uniquely up to unitary equivalence.*

For other representations of the Clifford algebra with a continuous ergodic measure <sup>(3)</sup>, such a simple classification is unknown.

4. Analyzing the example of von Neumann, which was already mentioned, one can easily verify that the factor-representation of the Clifford algebra of type  $\text{II}_1$  decomposes into a direct integral of irreducible representations for which  $\nu = 1$ , according to the classification of Gårding and Wightman <sup>(3)</sup>. It is of interest to determine whether irreducible representations for which  $\nu \neq 1$  will enter into the decomposition of a factor-representation of type  $\text{II}_1$ .

**Theorem 3.** *A factor-representation of type  $\text{II}_1$  for the Clifford algebra can be decomposed into a direct integral of irreducible representations for which  $\nu = 2^n$ , where  $n = 0, 1, 2, \dots$*

The proof of the theorem consists in constructing, for  $\nu = 2^n$  ( $n = 0, 1, \dots$ ), a factor-representation of type  $\text{II}_1$  for the Clifford algebra that has the properties of interest to us. We note that the very method of constructing factors of type  $\text{II}_1$  was previously unknown.

Let  $\Gamma$  be the space of sequences  $x = x_1x_2\dots$ , where  $x_i = 0$  or  $1$ . One may regard  $\Gamma$  as a group if componentwise addition modulo 2 is introduced for sequences. By  $\delta_k$  ( $k = 1, 2, \dots$ ) denote the sequence from  $\Gamma$  with a one in the  $k$ -th place and zeros in all the others. The Haar measure  $\mu$  of the group  $\Gamma$  coincides with Lebesgue measure under the natural mapping of  $\Gamma$  onto the unit interval.

Let  $H$  be the Hilbert space of vector-functions  $f(x, y)$  on  $\Gamma \times \Gamma$ , whose values belong to a  $2^n$ -dimensional complex pro-

space  $R_n$ . We define the scalar product in  $\tilde{H}$  by the formula

$$\langle f, g \rangle = \int_{\Gamma \times \Gamma} (f(x, y), g(x, y)) d\mu(x) d\mu(y),$$

where  $(\cdot, \cdot)$  is the scalar product in  $R_n$ .

We define a representation of the anticommutation relations  $\{A_k, B_k\}_1^\infty$  in  $\tilde{H}$  as follows:

$$\begin{aligned} A_k f(x, y) &= j_k(x) c_k(x + y) f(x + \delta_k, y), \\ B_k f(x, y) &= i^{-1} j_{k+1}(x) c_k(x + y) f(x + \delta_k, y) \quad (k = 1, 2, \dots), \end{aligned} \quad (3)$$

where  $j_k(x) = (-1)^{x_1 + \dots + x_{k-1}}$ , and  $\{c_k(x)\}_1^\infty$  are measurable functions on  $\Gamma$ , whose range consists of unitary operators in the space  $R_n$ . Similarly we define the representation  $\{\tilde{A}_l, \tilde{B}_l\}_1^\infty$ :

$$\begin{aligned} \tilde{A}_l f(x, y) &= j_l(y) c_l(x + y) f(x, y + \delta_l), \\ \tilde{B}_l f(x, y) &= i^{-1} j_l(y) c_l(x + y) f(x, y + \delta_l) \quad (l = 1, 2, \dots). \end{aligned} \quad (3')$$

Before explicitly writing the expression for  $c_k(x)$  ( $k = 1, 2, \dots$ ), we make a remark. Denote by  $\{p_s\}_1^{2n}$  an irreducible representation of the Clifford algebra in  $R_n$  with  $2n$  generators  $p_k = p_k^*$ ,  $p_k^2 = 1$  ( $k = 1, 2, \dots, n$ ),  $p_{kp}^l + p_{lp}^k = 0$  ( $l \neq k$ )<sup>4</sup>. Now put

$$c_{2nk+r}(x) = s_{2nk+r}(x) p_r, \quad (4)$$

where  $k = 0, 1, 2, \dots$ ;  $0 \leq r \leq 2n$ ,

$$s_{2nk+r}(x) = (-1)^{\sum_{i=1}^{2nk+r} x_i - \sum_{j=0}^k x_{2nj+r}}.$$

It is not hard to verify that the relations

$$\begin{aligned} c_k(x + \delta_k) &= c_k^*(x), \\ c_k(x) c_l(x + \delta_k) &= c_l(x) c_k(x + \delta_l) \quad (l \neq k) \end{aligned} \quad (5)$$

are satisfied.

From the results of (3) it follows that, for almost every  $y$ ,  $\{A_k, B_k\}_1^\infty$  in (3) define an irreducible representation, and for almost every  $x$ ,  $\{\tilde{A}_k, \tilde{B}_k\}_1^\infty$  also define an irreducible representation. On the basis of Theorem 3<sup>6</sup> we assert that the weakly closed ring  $M$  generated by the operators  $\{A_k, B_k\}_1^\infty$ , and also

the ring  $\tilde{M}$  generated by  $\{\tilde{A}_k, \tilde{B}_k\}_1^\infty$ , are factors. Moreover, it turns out that  $\tilde{M} = M'$  and  $M = \tilde{M}'$ .

Let us verify that  $M$  and  $\tilde{M}$  are factors of type  $\text{II}_1$ . For this it is enough to show<sup>5</sup> that on all operators from  $M$  one can define a linear homogeneous positive functional  $T$ , satisfying the conditions: 1)  $T(I) = 1$ , where  $I$  is the identity operator; 2)  $T(AB) = T(BA)$  ( $A, B \in M$ ); 3) if  $P$  is a projector from  $M$  and  $T(P) = 0$ , then  $P = 0$ .

Let  $e_1, \dots, e_{2^n}$  be an orthonormal basis in  $R_n$ , whose elements permute the operators  $p_1, \dots, p_{2^n}$ . Denote  $\varphi_0(x, y) \equiv 1$  and consider the vector-function  $f(x, y) = \varphi_0(x, y)e_1$ . Then the functional  $T(A) = \langle Af, f \rangle$ , where  $A \in M$ , has all the properties listed.

We note that if in our construction  $n = 0$ , then we obtain an example of von Neumann<sup>1</sup>. The case  $n \neq 0$  has not been considered previously.

It seems interesting that if, as the measure  $\mu(y)$ , one takes an arbitrary measure not equivalent to Lebesgue measure, but quasi-invariant and ergodic with respect to shifts by  $\delta_k$  ( $k = 1, 2, \dots$ ), then we obtain a factor-representation of type III for the Clifford algebra. For the case  $n \neq 0$  these representations, apparently, were not known.

The author expresses sincere gratitude to Prof. M. A. Naimark for his attention to the work.
