## ON THE NONEXISTENCE OF MAPPINGS OF CLASS $BL^{n/2}$ OF A BALL ONTO A DOMAIN

*(Presented by Academician M. A. Lavrent'ev, 17 IV 1967)*

1. A continuous vector function  $y = f(x)$ , defined in a domain  $D$  of  $n$ -dimensional Euclidean space  $E^n$  and with values in  $E^m$ , belongs to the class of functions  $BL_K^{n/2}$  if

$$I(f, D) = \int_D \left[ \sum_{i=1}^m \sum_{j=1}^n \left( \frac{\partial f_i}{\partial x_j} \right)^2 \right]^{n/2} dx \leq K < \infty,$$

where  $dx$  is the volume element in  $E^n$ , and the derivatives are understood in the sense of S. L. Sobolev.

If  $f \in BL_K^{n/2}$  for some  $K$ , then  $f \in BL^{n/2}$ . If the function  $y = f(x)$  realizes a homeomorphism of the ball  $D : |x| < R$  onto a domain  $\Delta$ , with  $f, f^{-1} \in BL_K^{n/2}$ , the domain  $\Delta$  contains the ball  $D_1 : |y| < \delta$ , and  $f(0) = 0$ , then the function  $f$  belongs to the class of functions  $[BL]_K^{n/2}$ . If  $f \in [BL]_K^{n/2}$  for some  $K$ , then  $f \in [BL]^{n/2}$ .

For  $n = m = 1$ , the integral  $I(f, D)$  gives the variation of the function  $f$  on the interval  $D$ . For  $n = m = 2$ ,  $I(f, D)$  is the usual Dirichlet integral, equal for conformal mappings to twice the measure of the domain  $f(D)$ . For quasiconformal mappings with bounded measure of the domain  $f(D)$ , the integral  $I(f, D)$  is bounded.

Of fundamental importance in studying the properties of mappings of class  $BL^{n/2}$  is the inequality of Theorem 2 of the work <sup>(1)</sup>. If, instead of  $I(f, D)$ , one substitutes into this inequality the integral

$$V_f(D) = \int_D \lambda_f^n(x) dx,$$

where

$$\lambda_f(x) = \overline{\lim}_{\Delta x \rightarrow 0} \frac{|f(x + \Delta x) - f(x)|}{|\Delta x|},$$

then it is preserved up to a constant factor, since

$$\lambda_f(x) \leq \left[ \sum_{i=1}^m \sum_{j=1}^n \left( \frac{\partial f_i}{\partial x_j} \right)^2 \right]^{1/2} \leq \sqrt{n} \lambda_f(x).$$

The quantity  $V_f(D)$  is naturally called the variation of the function over the domain  $D$ . The class of functions  $BL_K^{n/2}$  is thus a generalization of the class of functions of bounded variation (more precisely, of the class of functions of bounded variation, absolutely continuous inside the interval  $D$ ). The classes of functions  $BL_K^{n/2}$  and  $[BL]_K^{n/2}$  have many properties in common with the class of conformal mappings in the plane. The most essential difference is the absence of an analogue of the Riemann theorem for  $n \geq 3$ . The results given below show that, in the general case for  $n \geq 3$ , the question of the existence of mappings of a ball onto a domain within the class under consideration is of exceptional difficulty. For  $n = m = 2$ , mappings of this class were studied by J. Lelong-Ferrand <sup>(2)</sup> and G. D. Suvorov <sup>(3)</sup>. The study of the spatial case for  $n = m = 3$  was initiated in the works <sup>(4-7)</sup>, and was subsequently continued for  $n \geq 2$  and arbitrary  $m$  in <sup>(1, 8, 9)</sup>.

Below we shall use the following notation:  $\rho(M_1, M_2)$  is the distance between sets in  $E^m$ ;  $|x' - x''|$  is the distance between points-

in  $E^n$ ;  $\overline{M}$  is the closure of the set  $M$  in  $E^n$ ;  $\partial\Delta$  is the boundary of the domain  $\Delta$ ;  $d(M)$  is the diameter of the set  $M$  in  $E^n$ ;  $C_D(f, a, l)$  is the cluster set of the function  $f$  at the point  $a$  of the boundary of the domain  $D$  relative to the curve  $l \subset D$ , i.e., it is the set of limit points of sequences  $\{f(a_m)\}$ ,  $a_m \in l$  ( $m = 1, 2, \dots$ ),  $\lim_{m \rightarrow \infty} a_m = a$ .

2. For bounded domains  $\Delta \subset E^n$ , compact with respect to the relative distance <sup>(5)</sup> and belonging to the class of domains  $A_1(S)$  (for any sphere  $S$  in  $E^n$ , every component of the set  $S \cap \Delta$  divides the domain  $\Delta$  into two subdomains), the compactification of the domain by prime ends, analogous to the prime ends of Carathéodory <sup>(10)</sup>, is a compactum <sup>(8)</sup>. The prime ends of this class of domains contain 5 types of prime ends. To the 4 types in Carathéodory's classification there is added a prime end of the 5th type, whose body has a disconnected closed set of principal points.\* As the example of domains given below shows, for domains in  $E^n$  ( $n \geq 3$ ) all 5 types of prime ends are realized. On the other hand, by the corollary of Theorem 1, by means of a homeomorphism of class  $BL^{n/2}$  a ball cannot be mapped onto a domain having prime ends of the 5th type.

**Theorem 1.** *If the function  $y = f(x)$  realizes a homeomorphic mapping of class  $BL^{n/2}$  of the ball  $D : |x| < 1$  onto a bounded domain  $\Delta$ , then for every non-tangential curve  $l \subset D$  tending to a point  $a \in \partial D$ , the set  $C_D(f, a, l)$  coincides with the set  $|e|_1$  of principal points of the prime end  $e = f(a)$ .*

This theorem is an analogue of the well-known Lindelöf theorem for conformal mappings. For mappings of class  $BL$  it was established by J. Lelong-Ferrand <sup>(2)</sup>. The proof of this theorem is based on the inequality from <sup>(1)</sup> and the results from <sup>(8)</sup>.

**Corollary.** *There do not exist homeomorphic mappings of class  $BL^{n/2}$  of the ball  $D : |x| < 1$  onto a bounded domain  $\Delta$  having prime ends with a disconnected set of principal points.*

We give an example of domains in  $E^3$ , homeomorphic to the ball and compact with respect to the relative distance, which contain prime ends of the 5th type.

**Example 1.** Consider in  $E^3$  the cube  $R = \{x \in E^3 : 0 < x_i < 1 \ (i = 1, 2, 3)\}$  and the sets  $T_{mp} = \{x \in R : x_1 = 1/2^m 3^p\}$  ( $m, p = 1, 2, \dots$ ). Let  $F$  be an arbitrary closed set on the face  $T_0 = \{x \in \bar{R} : x_1 = 0\}$  of the cube  $R$ . We construct a domain  $\Delta$  having a prime end  $e$  such that  $|e| = T_0$ ,  $|e|_1 = F$ . We shall assume that  $F$  is an infinite set. For finite  $F$ , the constructions are carried out analogously.

Let  $\{a_m\}$  ( $m = 1, 2, \dots$ ),  $\{a_m\} \subset F$ , be some countable set of points of the face  $T_0$ , everywhere dense in  $F$ , with the points of  $\{a_m\}$  not lying on the edges of the cube  $R$ . Put  $Q_{mp} = \{x \in T_{mp} : |b_{mp} - x| < r_{mp}\}$ , where  $b_{mp} = a_m + c_{mp}$ ,  $c_{mp} = (1/2^m 3^p, 0, 0)$ ,  $r_{mp} = \min[1/2^m 3^p, \rho(a_m, \partial T_0)]$ , and  $\partial T_0$  is the boundary of  $T_0$ , considered as a plane set (in the plane  $x_1 = 0$ ). Then the set

$$\Delta = R \setminus \left[ \bigcup_{m,p=1}^{\infty} (T_{mp} \setminus Q_{mp}) \right]$$

is a bounded domain that is homeomorphic to the ball and compact with respect to the relative distance. Consider a sequence of sections  $\{q_n\}$  ( $n = 1, 2, \dots$ ), whose set coincides with the set of circles  $\{Q_{mp}\}$  ( $m, p = 1, 2, \dots$ ) and which are numbered in the order of approach to the face  $T_0$ . This sequence of sections defines a prime end  $e$  of the domain  $\Delta$  such that  $|e| = T_0$ ,  $|e|_1 = F$ . Thus, if

\* Let a prime end  $e$  of a domain  $\Delta$  be defined by means of a chain of subdomains  $\{g_m\}$ . The body of the prime end  $e$  is the set  $|e| = \bigcap_{m=1}^{\infty} \bar{g}_m$ . A point  $a \in |e|$  is called a principal point of the prime end  $e$  if there exists a chain of sections  $\{q_m\}$  defining the prime end  $e$  and contracting to the point  $a$ .

If  $F$  is a disconnected set, then the simple end  $e$  of the constructed domain  $\Delta$  will be of type 5. For  $n = 2$  the set of principal points of a simple end is always connected <sup>(10)</sup>.

3. Let us give a lower estimate for the quantity  $K$  for a mapping  $y = f(x)$  of class  $[BL]_K^{n/2}$  of the ball  $D$  onto the domain  $\Delta$ . This estimate will involve the function  $\psi(a, \Delta)$  of the variable  $a$ , which is defined as follows. Let  $G_a^0(\Delta)$  be the component of the set

$$G_a(\Delta) = \{x \in \Delta : \rho(x, \partial\Delta) > a\},$$

containing the point 0. Consider a point  $a \in \Delta \setminus G_a^0(\Delta)$  and define the function  $h(a, a)$  of the variable  $a$ :  $h(a, a) = \inf d(K)$ , where the infimum is taken over all continua  $K \subset \Delta$  separating the points  $a$  and 0 in  $\Delta$  and such that the sets  $K \cap G_a^0(\Delta)$  and  $K \cap \partial\Delta$  are nonempty. Then  $\psi(a, \Delta) = \sup h(a, a)$ , where the supremum is taken over all points  $a \in \Delta \setminus G_a^0(\Delta)$ .

**Theorem 2.** Let  $f(x) \in [BL]_K^{n/2}$ . Then the following lower estimate for the quantity  $K$  holds:

$$K \geq \sup_{0 < a < \delta} \min \left\{ \frac{\psi^n(a, \Delta)}{M_n n + \psi^n(a, \Delta)} \left[ \ln \frac{R^n}{M_n} + \ln \ln \frac{\delta}{a} \right], \frac{R^n}{M_n} \ln \frac{\delta}{a} \right\}, \quad (1)$$

where  $M_n$  is an absolute constant (1).

The proof is based on the inequality of Theorem 2 from (1).

**Corollary.** If

$$\overline{\lim}_{a \rightarrow 0} \psi(a, \Delta) \sqrt[n]{\ln \ln \frac{\delta}{a}} = \infty, \quad (2)$$

then there is no mapping  $y = f(x)$  of class  $[BL]^{n/2}$  of the ball  $D$  onto the domain  $\Delta$ .

**Remark.** Let  $y = f(x)$  be a  $Q$ -quasiconformal mapping of the ball  $D : |x| < R$  onto the domain  $\Delta$  of finite measure  $m\Delta$ , and let  $f(0) = 0$ . Then  $f(x) \in [BL]_K^{n/2}$ , where  $K \leq n^{n/2} Q^{n-1} \max(mD, m\Delta)$ , and hence

$$Q \geq [n^{n/2} \max(mD, m\Delta)]^{1/(n-1)} K^{1/(n-1)}. \quad (3)$$

Inequalities (1) and (3) give a lower estimate for the quasiconformality coefficient  $Q$  in terms of the structure of the domain  $\Delta$  and its boundary, which is expressed by means of the function  $\psi(a, \Delta)$ .

The corollary of Theorem 2 makes it possible to construct various domains  $\Delta \subset E^n$  ( $n \geq 3$ ), homeomorphic to a ball, onto which the ball cannot be mapped by means of functions of class  $[BL]^{n/2}$ , nor by quasiconformal mappings. It also makes it possible to construct sequences of domains  $\{\Delta_m\}$  such that there exist mappings of the ball  $\{f_m\}$ ,  $f_m(D) = \Delta_m$ ,  $f_m \in [BL]^{n/2}$  ( $m = 1, 2, \dots$ ), but the relation  $f_m \in [BL]^K$  is not satisfied for any  $K$ .

**Example 2.** Consider in  $E^3$  the cube

$$R = \{x \in E^3 : |x_i| < 1 \ (i = 1, 2, 3)\}.$$

Let  $\{a_m\}$  be a sequence of positive numbers  $0 < a_m < 1/3$  ( $m = 1, 2, \dots$ ), monotonically tending to 0. Put

$$B_m = \{x \in E^3 : |x_1| < b_m, a_{2m-1} < x_2 < a_{2m}, 1 \leq x_3 < b_m\},$$

where

$$b_m = \{\ln[-\ln(a_{2m} - a_{2m-1})]\}^{-1/6}.$$

The set  $\bar{\Delta}$ ,

$$\Delta = R \cup \left( \bigcup_{m=1}^{\infty} B_m \right),$$

is a domain homeomorphic to the closed ball; moreover, for this domain relation (2) holds, and hence there is no mapping of class  $[BL]^{3/2}$  of the ball onto this domain.

**Example 3.** Consider the cube

$$R = \{x \in E^3 : |x_i| < 1 \ (i = 1, 2, 3)\}.$$

Let  $\{a_m\}$  be a sequence of positive numbers  $2/3 \leq a_m < 1$  ( $m = 1, 2, \dots$ ), monotonically tending to 1. Put

$$C_m = \{x \in R : x_2 = a_m\}, \quad q_m = \{x \in C_m : |x_1| < a_{m+1} - a_m, |x_3| < b_m\},$$

where

$$b_m = \frac{1}{2} \exp[-\exp(a_{m+1} - a_m)^{-6}].$$

Then the set

$$\Delta = R \setminus \left[ \bigcup_{m=1}^{\infty} (C_m \setminus q_m) \right]$$

is a domain, homeomorphic to a ball and compact in the relative distance (it is constructed according to the type of the domains of Example 1). The domain  $\Delta$  has

a simple end of the second type, determined by the sequence of sections  $\{q_m\}$ , and for it relation (2) is satisfied.

**Example 4.** Consider a domain having the form of a wedge with zero angle  $\Delta = \{x \in E^3 : |x_1| < 1, |x_2| < 1, |x_3| < \varphi(x_2)\}$ , where  $\varphi(x_2) = \exp[-\exp(x_2+1)^{-6}]$ . It is easy to see that for this domain relation (2) is satisfied. A mapping of class  $[BL]^{n/2}$  onto a domain of this form will be impossible also in the case when, as the function  $\varphi(x_2)$ , one takes one having a higher order of contact with the axis  $Ox_2$  in comparison with the function chosen in this example.

We note that, for quasiconformal mappings, as F. W. Gehring and J. Väisälä established [11], a mapping onto a domain having a ridge directed outward, or a peak directed inward, is impossible. One can give examples of mappings

showing that, for mappings of class  $[BL]^{n/2}$ , such mappings are possible if the ridge and the peak are not too “sharp.”

**Example 5.** Put  $\Delta = \{x \in E^3 : |x_i| < 1 \ (i = 1, 2, 3)\}$ ,  $R_n = \{x \in \Delta : x_2 = 1 - 1/2n, -1 < x_3 \leq 0\}$  ( $n = 1, 2, \dots$ ), and consider the sequence of domains  $\{\Delta_n\}$ ,  $\Delta_n = \Delta \setminus R_n$ . Then there exists no number  $K$  and no sequence of mappings  $\{f_n(x)\}$  of the ball  $D$  onto the domains  $\Delta_n$ ,  $f_n(D) = \Delta_n$ , such that  $f_n(x) \in [BL]_K^{3/2}$  for every  $n$ .

**Example 6.** Put  $\Delta = \{x \in E^3 : |x_1| < 1, |x_2| < 1, -1 < x_3 < 2\}$ ,  $R'_n = \{x \in \Delta : x_2 \in [-1/2n, 1/2n], x_3 = 1\}$ ,  $\Delta_n = \Delta \setminus R'_n$ . Then there exists no sequence of mappings  $\{f_n(x)\}$  of the ball  $D$  onto the domains  $\Delta_n$ ,  $f_n(D) = \Delta_n$ , and no number  $K$  such that  $f_n \in [BL]_K^{3/2}$  for all  $n$ .
