# ON A GENERALIZATION OF KAKUTANI' S FIXED POINT THEOREM

(Presented by Academician L. V. Kantorovich, 2 IX 1968)

In the work <sup>(1)</sup>, I. L. Glicksberg gave a generalization of Kakutani' s fixed point theorem for a closed mapping of a convex compact set to the case of a locally convex linear topological space. In the present note this theorem is extended to a broader class of mappings.

Let  $X$  be a Hausdorff linear topological space and let  $S$  be a subset of  $X$ . A mapping  $\Phi : S \rightarrow X$  which carries points into nonempty sets is called closed if its graph

$$\bigcup_{x \in S} (x, \Phi(x))$$

is closed in  $X \times X$ . In terms of generalized sequences this definition is equivalent to one of the following assertions <sup>(1)</sup>:

- a) if  $x_\delta \rightarrow x_0$ ,  $y_\delta \in \Phi(x_\delta)$ ,  $y_\delta \rightarrow y_0$ , then  $y_0 \in \Phi(x_0)$ ;
- b) if  $x_\delta \rightarrow x_0$ ,  $y_\delta \in \Phi(x_\delta)$ , and  $y_0$  is a cluster point of the generalized sequence  $\{y_\delta\}$ , then  $y_0 \in \Phi(x_0)$ .

Glicksberg' s result is formulated as follows. If  $\Phi$  is a closed mapping in a locally convex Hausdorff linear topological space  $X$ , carrying points of a compact convex set  $S \subset X$  into convex subsets of  $S$ , then  $\Phi$  has a fixed point.

Everywhere below  $X$  is a locally convex Hausdorff linear topological space. As a fundamental system of neighborhoods of a point  $x \in X$  we shall consider the system

$$\mathcal{V}(x) = \{x + V \mid V \in \mathcal{V}(0)\},$$

where  $\mathcal{V}(0)$  is the system of all open, convex, and symmetric neighborhoods of zero. In those cases where  $\mathcal{V}(x)$  (respectively  $\mathcal{V}(x) \times \mathcal{V}(y)$ ) is considered as a directed set <sup>(2)</sup>, it is assumed that  $U_1 \leq U_2$ ,  $U_i \in \mathcal{V}(x)$ ,  $i = 1, 2$  (respectively  $(U_1, V_1) \leq (U_2, V_2)$ ,  $(U_i, V_i) \in \mathcal{V}(x) \times \mathcal{V}(y)$ ,  $i = 1, 2$ ), if and only if  $U_2 \subset U_1$  (respectively  $U_2 \subset U_1$  and  $V_2 \subset V_1$ ).

**Lemma 1.** *Suppose that for every  $x \in S$  the set  $\Phi(x)$  is closed and, moreover, for an arbitrary neighborhood of zero  $U$  there exists a neighborhood  $V \subset \mathcal{V}(x)$*

such that

$$\Phi(V \cap S) \subset \Phi(x) + U.$$

Then the mapping  $\Phi$  is closed.

**Proof.** Let  $x_\delta \rightarrow x$ ,  $y_\delta \in \Phi(x_\delta)$ ,  $y_\delta \rightarrow y$ , and  $y \notin \Phi(x)$ . By the closedness of  $\Phi(x)$ , there is a neighborhood of zero  $U \in \mathcal{V}(0)$  such that

$$(y + U) \cap \Phi(x) = \emptyset$$

or

$$(y + \frac{1}{2}U) \cap (\Phi(x) + \frac{1}{2}U) = \emptyset.$$

On the other hand, there exists a neighborhood  $V \in \mathcal{V}(x)$  such that from  $x_\delta \in V \cap S$  it follows that

$$\Phi(x_\delta) \subset \Phi(x) + \frac{1}{2}U,$$

whence  $y_\delta \notin y + \frac{1}{2}U$ . Consequently, the point  $y$  cannot be the limit of the generalized sequence  $\{y_\delta\}$ . The lemma is proved.

In what follows, the  $\Phi$  under consideration will be assumed to be a mapping from  $S$  into  $S$ , where  $S$  is a convex compact set, and by  $\bar{A}$  and  $\overline{\text{co}}A$  we shall mean the closure and the convex closure of the set  $A$ .

Let

$$\bar{\Phi}(x) = \bigcap_{V \in \mathcal{V}(x)} \overline{\Phi(V)}$$

and

$$F(x) = \overline{\text{co}}\bar{\Phi}(x),$$

where

$$\bar{\Phi}(V) = \{y \mid y \in \Phi(x), x \in V \cap S\}.$$

**Lemma 2.** *The mapping  $F$  has a fixed point.*

**Proof.** By Glicksberg's theorem, it suffices to show that the mapping  $F$  is closed. Choose arbitrarily a point  $x \in S$  and an (open) neighborhood  $U \in \mathcal{V}(0)$ . There exists an (open) neighborhood  $V_0 \in \mathcal{V}(x)$  such that

$$\Phi(V_0) \subset \Phi(x) + \frac{1}{2}U.$$

If this were not so, then the system consisting of the closed sets

$$S \setminus \overline{(\Phi(x) + \frac{1}{2}U)}$$

and  $\overline{\Phi(V)}$ ,  $V \in \mathcal{V}(x)$ , would be centered, which is impossible by compactness of  $S$  and the absence of a common point for the sets of this system. Let  $y \in V_0$ ,  $V \in \mathcal{V}(y)$ , and  $V \subset V_0$ . Then

$$\Phi(y) \subset \Phi(V) \subset \Phi(V_0) \subset \Phi(x) + \frac{1}{2}U \subset \overline{\text{co}}\bar{\Phi}(x) + \frac{1}{2}U.$$

Since the closure of the convex set

$$\overline{\text{co } \Phi(x)} + \frac{1}{2}U$$

is a convex set contained in

$$\overline{\text{co } \Phi(x)} + U,$$

we have

$$F(y) = \overline{\text{co } \Phi(y)} \subset \overline{\text{co } \Phi(x)} + U = F(x) + U.$$

Therefore, by Lemma 1, the mapping  $F$  is closed. The lemma is proved.

For an arbitrary point  $x \in X$  and a set  $B \subset X$ , by  $L(x, B)$  we shall denote the set of all points  $y \in X$  representable in the form

$$y = x + \lambda(z - x), \quad z \in B, \quad \lambda \geq 0,$$

i.e.,

$$L(x, B) = \bigcup_{\lambda \geq 0} [x + \lambda(B - x)].$$

It is obvious that if  $B \subset A$ , then  $L(x, B) \subset L(x, A)$ .

**Definition.** A mapping  $\Phi : S \rightarrow S$  will be called **partially closed** if from  $x_\delta \rightarrow x$ ,  $y_\delta \in \Phi(x_\delta)$ ,  $y_\delta \rightarrow y$  it follows that

$$L(x, y) \cap \Phi(x) \neq \emptyset.$$

Since for any cluster point  $y$  of the generalized sequence  $\{y_\delta\}$  one can select from  $\{y_\delta\}$  a generalized subsequence converging to  $y$ , in the preceding definition  $y$  may be regarded as a cluster point of  $\{y_\delta\}$ . In this way we obtain an equivalent definition of a partially closed mapping.

It is clear that every closed mapping is also partially closed.

**Theorem.** Every partially closed mapping  $\Phi$ , which maps the points of a compact convex set  $S \subset X$  into convex subsets of  $S$ , has a fixed point.

**Proof.** Suppose that for some open neighborhood of zero  $V_0$ , for all  $x \in S$  one has

$$(x + V_0) \cap \Phi(x) = \emptyset.$$

Denote by  $A(x)$  the closure of the set  $\Phi(x)$ . Obviously,

$$(x + V_0) \cap A(x) = \emptyset.$$

Let  $z \in V_0$ . Choose an open neighborhood of zero  $V \in \mathcal{V}(0)$  such that

$$z + V \subset V_0.$$

If  $y \in x + \frac{1}{2}V$ , then  $x \in y + \frac{1}{2}V$ , and

$$x + z + \frac{1}{2}V \subset y + z + V \subset y + V_0.$$

Consequently,

$$(x + z + \frac{1}{2}V) \cap \Phi(x + \frac{1}{2}V) = \emptyset$$

and

$$x + z \notin \overline{\Phi(x + \frac{1}{2}V)},$$

whence  $x + z \notin \overline{\Phi(x)}$ , or

$$(x + V_0) \cap \overline{\Phi(x)} = \emptyset. \quad (1)$$

We now show that

$$\overline{\Phi(x)} \subset L(x, \Phi(x)). \quad (2)$$

Indeed, let  $y \in \overline{\Phi(x)}$ . For an arbitrary

$$\delta = (U, V) \in \mathcal{V}(x) \times \mathcal{V}(x)$$

we have  $y \in \Phi(V)$ , i.e.,

$$U \cap \Phi(V) \neq \emptyset.$$

Let  $x_\delta \in V$ ,  $y_\delta \in U \cap \Phi(x_\delta)$ . Then  $x_\delta \rightarrow x$ ,  $y_\delta \rightarrow y$ , and, by partial closedness of the mapping  $\Phi$ ,

$$L(x, y) \cap \Phi(x) = \emptyset,$$

i.e., for some  $\lambda > 0$  we shall have

$$z = x + \lambda(y - x) \in \Phi(x),$$

or

$$y = x + \frac{1}{\lambda}(z - x) \in L(x, \Phi(x)).$$

Thus, from (1) and (2) we obtain

$$\overline{\Phi(x)} \subset S \cap L(x, \Phi(x)) \setminus (x + V_0). \quad (3)$$

By virtue of the boundedness of the set  $S$ , there exists  $\lambda_0 > 0$  such that  $\lambda_0(S - x) \subset V_0$ . Then for  $\lambda < \lambda_0$  we have  $x + \lambda(A(x) - x) \subset x + V_0$  and, taking (1) into account,  $S \cap [x + \frac{1}{\lambda}(A(x) - x)] = \emptyset$ . Consequently,

$$S \cap L(x, \Phi(x)) \setminus (x + V_0) \subset \bigcup_{\lambda_0 \leq \lambda \leq 1/\lambda_0} [x + \lambda(A(x) - x)] = D. \quad (4)$$

Since the set  $A(x)$  is convex,  $D$  is also convex. Moreover, being the image of the compact set  $[\lambda_0, 1/\lambda_0] \times A(x)$  under the continuous mapping  $(\lambda, z) \rightarrow x + \lambda(z - x)$ ,  $D$  is closed. Taking (3) and (4) into account, we have  $\text{co } \overline{\Phi(x)} \subset D$ . Since  $x \notin D$ , it follows that  $x \notin \text{co } \overline{\Phi(x)}$  for every  $x \in S$ , which contradicts Lemma 2.

Suppose now that for every neighborhood of zero  $V \in \mathcal{V}(0)$  there exists a point  $x_V \in S$  for which

$$(x_V + V) \cap \Phi(x_V) \neq \emptyset.$$

Let  $y_V = x_V + z_V \in \Phi(x_V)$ ,  $z_V \in V$ . The generalized sequence  $\{x_V\}$  has an accumulation point  $x \in S$ . Consider the set  $\Delta = \{(U, V) \mid x_V \in U, (U, V) \in \mathcal{V}(x) \times \mathcal{V}(0)\}$ . Since  $x$  is an accumulation point for  $\{x_V\}$ ,  $\Delta$  forms a direction cofinal with  $\mathcal{V}(x) \times \mathcal{V}(0)$ . For  $\delta = (U, V) \in \Delta$ , putting  $x_\delta = x_V$  and  $z_\delta = z_V$ , we shall have  $x_\delta \rightarrow x$ ,  $z_\delta \rightarrow 0$ , and  $y_\delta = x_\delta + z_\delta \rightarrow x$ . Then, by virtue of the partial closedness of the mapping  $\Phi$ , we have  $L(x, x) = x \in \Phi(x)$ . The theorem is proved.
